Cover photos of the Goldsworthy Desalter in Torrance, CA, which was expanded in 2018 to double the capacity for removing brackish groundwater and turning it into fresh drinking water. Photos show the front of the Goldsworthy facility, a reverse osmosis booster pump within the facility, and the two new extraction wells, one of which is located in the adjacent City Yard and the other about 1,500 feet to the northwest in Delthorne Park.

Executive Summary

The Water Replenishment District of Southern California (WRD or the District) was formed in 1959 to manage the groundwater replenishment and groundwater quality activities for 4 million people in 43 cities that overlie the Central Basin and West Coast Basin (CBWCB) in southern Los Angeles County. WRD's service area encompasses nearly the entire Central Basin and all of the West Coast Basin. These two basins currently supply over 40 percent of the water used by the population in the region. Our mission is to protect and preserve high-quality groundwater in the basins through innovative, cost-effective, and environmentally sensitive management practices for the benefit of residents and businesses within the WRD service area.

WRD has been monitoring the CBWCB for over 50 years, and this year's annual report presents the most comprehensive information to date utilizing WRD's network of aquifer-specific monitoring wells and in-depth water quality analysis. The Regional Groundwater Monitoring Program (RGWMP) currently consists of a network of 324 monitoring wells at 58 locations throughout the District. To that end, WRD has a dedicated Board and staff that engage in year-round activities to closely monitor groundwater conditions. The District performs extensive collection, analysis, and reporting of groundwater data to ensure proper resource management. The publication of this Regional Groundwater Monitoring Report (RGWMR) is one result of those efforts, it presents information on groundwater levels and groundwater quality over the past Water Year (WY) which runs from October 1 through September 30. This current report is for WY 2016-17. Detailed information is presented in the body of the report with a summary below:

Groundwater Levels

Across the WRD service area water levels have generally increased over the water year, although in some areas they have decreased and in others they have remained essentially unchanged. The increase in water levels can be partly attributed to above average precipitation over the WRD service area in WY 2016-17. Water level changes in specific areas is discussed below.

In the Central Basin, groundwater levels have generally increased in WY 2016-17. In the unconfined Montebello Forebay water levels have increased; in the vicinity of the spreading grounds they have increased by as much as 29 feet, along the western and southern reaches of the Forebay they have increased as much as 12 feet, and to the east they have increased by 20 feet. Across much of the unconfined Los Angeles Forebay water levels have increased in WY 2016-17 by about 3 feet; however, in the central portion of the Forebay water levels decreased as much as 3 feet and appear to be influenced by a localized area of groundwater depression. Whittier Area water levels have also increased in WY 2016-17; in the west they have increased by as much as 20 feet, in the east they are essentially unchanged from WY 2015-16.

Water levels have generally increased across the rest of the Central Basin in WY 2016-17. In the north portion of the Central Basin Pressure Area (CBPA) water levels have increased this year by as much as 10 feet; along the eastern edge of the CBPA water levels are as much as 27 feet higher than they were last year. Across most of the rest of the CBPA water levels are about 1 to 3 feet higher than they were last year. In the southern portion of the CBPA, along the Northeast Uplift, water levels are relatively unchanged from WY 2015-16.

In the West Coast Basin, changes in water levels are variable. Water levels increased by as much as 5 feet across most of the coastal area and within much of the Long Beach Plain during WY 2016-17. Water levels did not change significantly over portions of the Carson/Torrance area and north into Lawndale and southwest Los Angeles. However, water levels increased by as much as 5 feet in Lomita and the western portions of Torrance. In the Gardena area a localized pumping hole shows water level decreases of as much as 11 feet; water level decreases of between 1 and 5 feet in the Hawthorne and northern Carson areas appear to be associated with that pumping hole.

District wide, groundwater levels rose more than 7 feet, although across the Montebello

Forebay region water levels rose an average of nearly 17 feet. Overall groundwater storage gain across the District was 84,400 Acre-Feet (AF); 77,400 AF of that storage was gained in the Montebello Forebay. Groundwater storage gain in the Los Angeles Forebay was 2,700 AF, 1,200 AF of storage was gained in the Central Basin Pressure Area, and the Whittier Area saw an increase of 3,100 AF. The West Coast Basin did not have any appreciable change in storage over WY 2016-17.

Groundwater Quality

Annually, WRD collects over 600 groundwater samples from its monitoring well network and analyzes them for more than 100 water quality constituents to produce over 60,000 individual data points to help track the water quality in the basins. By analyzing and reviewing the results on a regular basis, new and emerging water quality concerns can be identified and managed effectively.

The reporting of this monitoring and analysis include data tables, maps, and trend graphs which are presented in this report. Overall, the groundwater in the WRD service area continues to be of high quality, suitable for potable and non-potable uses, and continues to meet our high standards. There are however, localized areas of marginal to poor water quality that go untapped or may require treatment prior to use. The source of the poor water quality in these areas can be from natural or anthropogenic causes. WRD will continue to focus on these areas to monitor trends and look for ways to mitigate any contamination that makes the groundwater unsuitable for use.

Analysis for this report uses water quality maps and trend graphs to focus on 12 key water quality constituents to represent overall groundwater quality in the basins, including total dissolved solids (TDS), iron, manganese, chloride, nitrate, trichloroethylene (TCE), tetrachloroethylene (PCE), arsenic, perchlorate, hexavalent chromium, 1,4-Dioxane and Tertiary butyl alcohol (TBA). TDS, where elevated, is typically present along with chloride as an indicator of historical seawater intrusion or groundwater from older marine sediments. The most prevalent water quality issue in WRD's service area is manganese, a naturally-occurring element that at elevated concentrations may impact the aesthetics of

groundwater and can require treatment prior to delivery as drinking water. Elevated, naturally-occurring arsenic impacts a number of wells in WRD's service area. TCE and PCE that can leak into groundwater from industrial and commercial facilities, have also impacted wells in the District and are closely monitored. Chemicals of emerging concern (CECs) including hexavalent chromium, perchlorate, 1,4-Dioxane and TBA have relatively new drinking water standards and WRD has performed baseline screening and analysis of these CECs to assess the potential threat to the groundwater in WRD's service area.

Consistent with WRD's mission to provide, protect, and preserve high quality groundwater, and as required by the State's Recycled Water Policy, a Salt and Nutrient Management Plan (SNMP) has been developed and a Basin Plan Amendment was subsequently adopted to ensure the long-term viability of groundwater in the CBWCB. Through the RGWMP, 13 key WRD nested monitoring wells were selected to track salt and nutrient water quality trends throughout the District and in the most critical areas of the basins, including areas near water supply wells and groundwater recharge projects that utilize recycled water (i.e. the seawater intrusion barriers and the Montebello Forebay Spreading Grounds). Overall, the data show that salt and nutrient concentrations in groundwater are stable and in some locations improving which can be attributed to past and current groundwater management practices. Based on the existing water quality of the CBWCB and future groundwater quality as estimated and presented in the SNMP, existing and planned implementation measures appear adequate to manage salt and nutrient loading on a sustainable basis.

Upcoming Activities and Challenges Ahead

WRD remains committed to its statutory charge to protect and preserve groundwater resources in its service area. To that end, WRD plans an expansion of its groundwater monitoring well network to fill data gaps in the Central Basin and to install new monitoring points in the North Central Basin. WRD will continue to perform other projects and programs to meet its charge. One of the biggest challenges currently facing the District is the rising cost and unreliability of imported water for groundwater replenishment. The District seeks to eliminate its reliance on imported water for replenishment and looks to

expand local sources including storm water and recycled water. This initiative is our Water Independence Now (WIN) program, which includes as a key component, the Albert Robles Center for Water Recycling and Environmental Learning (ARC) (formerly known as the Groundwater Reliability Improvement Project (GRIP)). ARC's main purpose is to ensure reliable sources of high quality replenishment water for groundwater users in the WRD service area.

WRD will continue to use the data generated by the RGWMP along with WRD's Geographic Information System (GIS) capabilities to address current and potential upcoming issues related to water quality and groundwater replenishment in its service area. WRD staff will be working on refining the hydrogeologic conceptual model of the CBWCB using data from the RGWMP along with an update to the groundwater model, expected to be finalized in 2018, that has been developed by the United States Geological Survey (USGS) to improve the framework for understanding the groundwater system and for use as a planning tool.

WRD will continue to be proactively involved in the oversight of contaminated sites that threaten groundwater within its service area and will fund the Safe Drinking Water Program to address impacted groundwater. WRD will continue efforts under its Groundwater Contamination Prevention Program in order to minimize or eliminate threats to groundwater supplies including continued administration of the CBWCB Groundwater Contamination Forum, consisting of key stakeholders focused on expediting the investigation and cleanup of high-priority contaminated groundwater sites. Currently, there is a list of 49 high-priority sites across WRD's service area. WRD will continue to monitor the saline plume in the West Coast Basin and will update the saline plume map with new data collected from increased sampling.

On November 4, 2009, the State Legislature amended the Water Code with SBx7-6, mandating a statewide program to track seasonal and long-term trends in groundwater elevations in California's groundwater basins. The California Department of Water Resources (DWR) developed the California Statewide Groundwater Elevation Monitoring

(CASGEM) program to address the Water Code amendment. In October 2011, WRD was assigned as the Designated Monitoring Entity (DME) responsible for collecting and reporting CBWCB groundwater level data to CASGEM. Through the RGWMP, WRD will continue to collect CBWCB groundwater level data, track seasonal and long-term trends, and provide data to the CASGEM program.

WRD has worked closely with various stakeholders to comply with the Sustainable Groundwater Management Act (SGMA). SGMA recognizes groundwater as an integral part of the state's water supply and provides a framework for managing groundwater in a sustainable way throughout California. SGMA applies to two areas located within the geologic boundaries of the Central Basin but outside of its adjudicated boundaries. To comply, a working group was formed to conduct a groundwater sustainability analysis with various interested stakeholders including the City of Beverly Hills, City of Culver City, Los Angeles County Department of Public Works (LACDPW), Los Angeles Department of Water and Power (LADWP), Golden State Water Company (GSWC), and WRD. On behalf of the stakeholder group, WRD submitted the required analysis to the California Department of Water Resources (DWR) in the document, "Alternative Analysis for the Central Basin – Los Angeles County, California", dated December 16, 2016. WRD expects to receive an evaluation update from the DWR in 2018.

Further information is available on the WRD web site at ***http://www.wrd.org***, or by calling WRD at (562) 921-5521. WRD welcomes any comments or suggestions to this RGWMR.

WY	Water Year

SECTION 1
INTRODUCTION

The Water Replenishment District of Southern California (WRD or the District) manages groundwater replenishment and water quality activities for the Central Basin and West Coast Basin (CBWCB) in southern Los Angeles County (**Figure 1.1**). WRD's service area encompasses nearly the entire Central Basin and all of the West Coast Basin. Our mission is to protect and preserve high-quality groundwater in the basins through innovative, cost-effective, and environmentally sensitive management practices for the benefit of residents and businesses within WRD's service area.

As part of accomplishing this mission, WRD maintains a thorough and current understanding of groundwater conditions in its service area and strives to predict and prepare for future conditions. This is achieved through groundwater monitoring, modeling, and planning, which provide the necessary information to determine the "health" of the basins. This information in turn provides WRD, the groundwater pumpers WRD's service area, other interested stakeholders, and the public with the knowledge necessary for responsible water resources planning and management. Each year WRD compiles the most recently collected information into a Regional Groundwater Monitoring Report (RGWMR) that presents the most current understanding of conditions in the basins; the RGWMR is just one of the efforts by WRD to fulfill its mission.

1.1 BACKGROUND OF THE REGIONAL GROUNDWATER MONITORING PROGRAM

Since its formation in 1959, WRD has been actively involved in groundwater replenishment, water quality monitoring, contamination prevention, data management, and data publication. Historical over-pumping of the CBWCB caused overdraft, seawater intrusion, and other groundwater management problems related to supply and quality. Adjudication of the basins in the early 1960s set a limit on allowable groundwater extractions in order to control the over-pumping. Concurrent with adjudication, WRD was

formed to address issues of groundwater recharge and groundwater quality. The Regional Groundwater Monitoring Program (RGWMP) is an important District program which tracks groundwater levels and groundwater quality in the WRD service area to ensure the sustainability of this groundwater resource.

Prior to 1995, WRD relied heavily upon groundwater data collected, interpreted, and presented by other entities such as the Los Angeles County Department of Public Works (LACDPW), the California Department of Water Resources (DWR), and the private sector for understanding basin conditions. However, these data were collected primarily from production wells, which are typically screened across multiple aquifers to maximize water inflow. The result is a mixing of waters from different aquifers into a single well casing, causing an averaging of water levels and water quality.

In order to obtain more accurate data for specific aquifers from which to infer localized water level and water quality conditions, depth-specific (nested) monitoring wells that tap discrete aquifer zones are necessary. **Figure 1.2** illustrates the capabilities of nested monitoring wells to assess individual aquifers compared to typical production wells.

Data for the RGWMRs are generally provided for a Water Year (WY), which occurs from October 1 to the following September 30. During WY 1994-95, WRD and the United States Geological Survey (USGS) began a cooperative study to improve the understanding of the geohydrology and geochemistry of the CBWCB. The initial study was documented in USGS Water Resources Investigations Report 03-4065, *Geohydrology, Geochemistry and Ground-Water Simulation-Optimization of the Central Basin and West Coast Basin, Los Angeles County, California* (Reichard et al. 2003). That study is the nucleus of WRD's ongoing RGWMP. In addition to compiling existing available data, that study recognized that the sampling of production wells did not adequately characterize the layered multiple aquifer systems of the CBWCB. The study focused on new data collection through drilling and construction of nested groundwater monitoring wells and conducting depth-specific groundwater monitoring.

Figure 1.3 is a District map showing the locations of wells in WRD's nested monitoring well network. Currently, there are 324 wells at 58 locations; these wells allow WRD to comprehensively monitor groundwater conditions in its service area. A listing and depth details for the WRD wells are presented in **Table 1.1.**

An *Annual Report on the Results of Water Quality Monitoring* (*Annual Report*) was published by WRD each year for WYs 1972-73 through 1994-95, and was based on a basinwide monitoring program outlined in the *Report on Program of Water Quality Monitoring* (Bookman-Edmonston Engineering, Inc., January 1973). The latter report recommended a substantial expansion of the then-existing program, particularly the development of a detailed and intensive program for the monitoring of groundwater quality in the Montebello Forebay. The RGWMP was designed to serve as an expanded, more representative basinwide monitoring program for the CBWCB. This RGWMR is published in lieu of the previous *Annual Reports*.

On November 4, 2009 the State Legislature amended the Water Code with SBx7-6, mandating a statewide groundwater elevation monitoring program to track seasonal and long-term trends in California's groundwater basins. In accordance with this amendment, DWR developed the California Statewide Groundwater Elevation Monitoring (CASGEM) program. In October 2011, WRD was assigned as the Designated Monitoring Entity responsible for collecting and reporting CBWCB groundwater level data to CASGEM. Through the RGWMP, WRD collects groundwater level data from within its service area, tracks seasonal and long-term trends and provides that data to the CASGEM program.

1.2 CONCEPTUAL HYDROGEOLOGIC MODEL

As described above, the RGWMP has changed the focus of groundwater monitoring efforts in the WRD service area from production wells with averaged groundwater level and groundwater quality information, to a layered multiple aquifer system with individual zones of groundwater quality and groundwater levels. WRD views each aquifer as a significant component of the groundwater system and recognizes the importance of the

interrelationships between aquifers. The most accepted hydrogeologic description of the basins and the names of water-bearing zones are provided in California Department of Water Resources, *Bulletin No. 104: Planned Utilization of the Ground Water Basins of the Coastal Plain of Los Angeles County, Appendix A–Ground Water Geology* (DWR, 1961). WRD generally follows the naming conventions defined in Bulletin 104; however, in some cases WRD's in-house interpretation has resulted in aquifer classifications that differ from those predicted by that report.

The locations of idealized geologic cross-sections AA' and BB' through the WRD service area are shown on **Figure 1.3**. These cross-sections are presented on **Figures 1.4** and **1.5**, respectively. These cross-sections are modified versions of cross-sections presented in Bulletin 104, and illustrate a simplified aquifer system in the CBWCB. The main potable production aquifers described in Bulletin 104 are shown, including the deeper Lynwood, Silverado, and Sunnyside aquifers of the lower Pleistocene San Pedro Formation. Other shallower aquifers, which locally produce potable water, include the Gage and Gardena aquifers of the upper Pleistocene Lakewood Formation. Also shown on the geologic sections are the aquitards separating aquifers. Throughout this report the aquifers shown on the geologic sections are referred to as discrete groundwater zones. Many references are made to the Silverado Aquifer, typically thought of as the main producing aquifer in the CBWCB. Substantial pumping can come from the Lynwood and Sunnyside aquifers as well.

1.3 GIS DEVELOPMENT AND IMPLEMENTATION

WRD uses a Geographic Information System (GIS) as a tool for groundwater management in its service area. Much of the GIS data was compiled during the WRD/USGS cooperative study. The GIS links spatially-related information (e.g., well locations, geologic features, cultural features, contaminated sites) to data on well production, water quality, water levels, and replenishment amounts. WRD uses industry standard Esri ArcGIS® software for data analysis and preparation of spatially-related information (maps and graphics tied to data).

WRD utilizes Global Positioning System (GPS) technology to determine and document the locations of basinwide production wells, nested monitoring wells, and other geographic features for use in the GIS database. During WY 2015-16, WRD updated and modernized its database so that a consistent reference surface datum is used when describing the mean sea level elevation at each monitoring well. This update required a re-survey of the measurement reference point at each of WRD's wells relative to the North American Vertical Datum of 1988 (NAVD88) reference plane. This update resulted in adjustment for some of the "reference point elevations" that have previously been used and published by WRD. Current NAVD88 reference point elevations are listed in **Table 2.1**.

WRD is constantly updating the GIS with new data and newly-acquired archives of data acquired by staff or provided by pumpers and other agencies. The GIS is a primary tool for WRD and other water-related agencies to more accurately track current and past use of groundwater, track groundwater quality, and project future water demands, thus allowing improved management of the basins.

In early 2003, WRD completed the development of its Internet-based GIS and Interactive Well Search Tool, which was made available to the public for access to CBWCB groundwater information. WRD's internet-based GIS can be accessed through our GIS website at *http://gis.wrd.org*. The website provides the public with access to much of the water level and water quality data contained in this report. The well information on the website can be accessed through interactive maps or text searches, and the results can be displayed in both tabular and graphical formats.

1.4 SCOPE OF REPORT

This report updates information on groundwater conditions in the WRD service area for WY 2016-17, and discusses the status of the RGWMP. Section 1 provides an overview of WRD and its RGWMP. Section 2 discusses district-wide groundwater levels for WY 2016-17. Section 3 presents water quality data for the WRD nested monitoring wells,

basin-wide production wells, and replenishment water. Section 4 summarizes salt and nutrient management in the CBWCB and presents water quality trends for TDS and chloride. Section 5 summarizes findings from the evaluation of data in this report. Section 6 presents future regional groundwater monitoring and related activities. Section 7 lists the references used in this report. Tables and figures are presented in separate sections at the end of the report. This WY 2016-17 WRD RGWMR, along with previously published reports for past WYs, can be viewed online and downloaded in Portable Document Format (PDF) from the WRD website at *http://www.wrd.org.*

SECTION 2
GROUNDWATER LEVELS

Groundwater levels are a direct indication of the amount of groundwater in the basins. Tracking groundwater levels identify areas of recharge and discharge from the basins. Differences in groundwater levels suggest which way groundwater is moving so that recharge water or contaminants can be tracked. WRD uses groundwater levels to determine when additional replenishment water is required and to calculate groundwater storage changes. Groundwater levels can also be used to identify possible source areas and pathways for seawater intrusion, and to demonstrate the effectiveness of seawater barrier injection wells. Groundwater levels are partly dependent on regional precipitation. Above average rainfall across the WRD service area in WY 2016-17 helped increase the groundwater elevations at many of WRD's nested wells to levels that are much higher than have been measured over the past several years.

WRD tracks groundwater levels throughout the year by measuring the depth to water in monitoring wells and production wells located throughout its service area. Groundwater elevations are calculated by comparing depth to water measurements to the mean sea level elevation at the measuring point of each well. **Table 2.1** presents manual groundwater level measurements collected from the District's nested monitoring wells during WY 2016-17. In order to capture the daily and seasonal variations in water levels, WRD has installed automatic data-logging equipment in most of the nested monitoring wells to collect water levels more frequently than practical for manual measurements. WRD also obtains water level data from cooperating entities such as area pumpers, DWR, and LACDPW, who collect water levels from their wells. These data are entered into WRD's GIS water level database for archiving and analysis.

From the water level database, a groundwater elevation contour map, change in groundwater level map, and groundwater elevation hydrographs were prepared for selected

wells to aid in analysis and illustrate the current and historical groundwater conditions in the basins. These are presented and explained in the following sections.

2.1 GROUNDWATER ELEVATION CONTOURS

A contour map showing the groundwater elevations measured across the WRD service area in the deeper, main producing aquifers during the Fall of 2017 is presented in **Figure 2.1**. The Fall 2017 Contour Map shows that in the Central Basin water levels range from highs in excess of 150 feet above mean sea level (msl) to lows in excess of 100 feet below msl. The highest water levels are in the Montebello Forebay; water levels decrease to the south and west towards the Long Beach area, the Newport-Inglewood Uplift, and the Los Angeles Forebay.

In the West Coast Basin, water levels range from highs of nearly 10 feet above msl to lows of about 75 feet below msl. The highest water levels are along the West Coast Basin Seawater Intrusion Barrier; they decrease to the east where they are at their lowest elevation in the City of Gardena between the Charnock Fault and Newport-Inglewood Uplift, both of which are geologic structural features that partially restrict groundwater flow.

2.2 CHANGES IN GROUNDWATER LEVELS

Groundwater levels measured in Fall 2017 compared to those measured in Fall 2016 are illustrated on **Figure 2.2**, which is a groundwater level change map. During WY 2016-17 groundwater levels across the WRD service area have generally increased, although results vary; in some areas they have decreased and in others they have remained essentially unchanged.

In the Central Basin, groundwater levels have generally increased in WY 2016-17. In the unconfined Montebello Forebay water levels have increased; in the vicinity of the spreading grounds they have increased by as much as 29 feet, along the western and southern reaches of the Forebay they have increased as much as 12 feet, and to the east

they have increased by 20 feet. Across much of the unconfined Los Angeles Forebay water levels have increased in WY 2016-17 by about 3 feet; however, in the central portion of the Forebay water levels decrease as much as 3 feet and appear to be influenced by a localized area of groundwater depression. Whittier Area water levels have also increased in WY 2016-17; in the west they have increased by as much as 20 feet, and in the east they are essentially unchanged from WY 2015-16.

Water levels have generally increased across the rest of the Central Basin in WY 2016-17. In the north portion of the Central Basin Pressure Area (CBPA) water levels have increased this year by as much as 10 feet; along the eastern edge of the CBPA water levels are as much as 27 feet higher than they were last year. Across most of the rest of the CBPA water levels are about 1 to 3 feet higher than they were last year. In the southern portion of the CBPA, along the Northeast Uplift, water levels are relatively unchanged from WY 2015-16.

In the West Coast Basin, changes in water levels are variable. Water levels increased by as much as 5 feet across most of the coastal area and within much of the Long Beach Plain during WY 2016-17. Water levels did not change significantly over portions of the Carson/Torrance area and north into Lawndale and southwest Los Angeles. However, water levels increased by as much as 5 feet in Lomita and the western portions of Torrance. In the Gardena area a localized pumping hole shows water level decreases of as much as 11 feet; water level decreases of between 1 and 5 feet in the Hawthorne and northern Carson areas appear to be associated with that pumping hole.

District wide, groundwater levels rose more than 7 feet, although across the Montebello Forebay region water levels rose an average of nearly 17 feet. Overall groundwater storage gain across the District was 84,400 AF; 77,400 AF of that storage was gained in the Montebello Forebay. Groundwater storage gain in the Los Angeles Forebay was 2,700 AF, 1,200 AF of storage was gained in the Central Basin Pressure Area, and the Whittier Area saw an increase of 3,100 AF. The West Coast Basin did not have any appreciable change in storage over WY 2016-17.

2.3 GROUNDWATER LEVEL HYDROGRAPHS

WRD relies on hydrographs to track the changes in water levels in wells over time. Hydrographs reveal the seasonal fluctuations of water levels caused by variations in natural and artificial recharge, and the effects of pumping and other basin discharge. Historical hydrographs of water level data going back to the 1930s and 1940s in the Montebello Forebay, Los Angeles Forebay, Central Basin Pressure Area, and West Coast Basin are presented in the annual WRD Engineering Survey and Report (ESR). The ESR hydrographs illustrate the general history of groundwater conditions in the CBWCB and results show: 1) Steep water level declines occurred in the 1930s through 1950s as a result of excessive pumping (overdraft); 2) In the mid-1950s to early 1960s, there was a reversal in this downward trend due to initiation of groundwater management policies; 3) Water levels increased through the 1970s and 1980s in response to reduced pumping, artificial replenishment by WRD, and seawater barrier construction and injection; and 4) Over about the past 7 water years , water levels have overall generally decreased in the Montebello Forebay as well as the rest of the Central Basin.

Hydrographs for WRD nested monitoring wells that plot water level measurements from individual aquifer zones against time provide WRD with a graphical method to observe changes in water level and can aid in identifying current and historic trends in aquifer conditions. The data for these annual hydrographs are collected from WRD's network of nested monitoring wells. **Figures 2.3 through 2.15** are hydrographs of 13 key WRD nested monitoring wells, including three in the Montebello Forebay, one in the Los Angeles Forebay, four in the Central Basin Pressure Area, one in the Whittier Area, and four in the West Coast Basin, respectively. Locations of the 13 key nested monitoring wells are shown on **Figure 1.3**. These hydrographs illustrate that there can be distinct groundwater elevation differences, up to 90 feet, between adjacent aquifers at a single nested well location. The differences in elevation are influenced by variable discharge (i.e. pumping from wells) and recharge (i.e. injection, percolation, or underflow) and the degree of hydraulic communication between aquifers. These hydrographs are particularly useful in

identifying the zones that are in the main flow system and the zones that show the greatest depth and seasonal fluctuations in groundwater levels during the WY. A discussion of the hydrographs shown on **Figures 2.3 through 2.15** are presented in the following sections.

2.4 GROUNDWATER LEVELS IN THE MONTEBELLO FOREBAY

Figure 2.3 is a hydrograph for WRD's Rio Hondo #1 key nested monitoring well located in the Montebello Forebay at the Rio Hondo Spreading Grounds. There are six individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Gardena, Lynwood, Silverado, and Sunnyside (3 deepest zones), with depths ranging from 140 to 1,130 feet below ground surface (BGS). Because this well is located in the Montebello Forebay, where the aquifers are in general hydraulic communication with each other, water level responses in all of the aquifers are similar. Seasonal highs and lows are in response to recharge and pumping. Groundwater elevations are lowest in Zone 4, the Silverado Aquifer, suggesting that this aquifer is the most heavily pumped in the area. Water levels in Zone 4 increased about 16 feet over the past WY and are the highest levels recorded in the past three years.

Figure 2.4 is a hydrograph for WRD's Pico #2 key nested monitoring well, also located in the Montebello Forebay adjacent to the San Gabriel River and just south of the San Gabriel River Spreading Grounds. There are six individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Gaspur, Lynwood, Silverado, and Sunnyside (3 deepest zones), with depths ranging from 100 to 1,200 feet BGS. Groundwater elevations are lowest in Zones 1 and 2, both in the Sunnyside Aquifer, suggesting that the Sunnyside Aquifer is the most heavily pumped in this area. Water levels in Zone 3 increased about 19 feet over the past WY and are the highest levels recorded in the past five years.

Figure 2.5 is a hydrograph for WRD's Norwalk #2 key nested monitoring well located in the Montebello Forebay, 3.5 miles south of the San Gabriel River Spreading Grounds. There are six individual wells (zones) that are screened in the following aquifers (from

shallowest to deepest): Exposition, Gardena, Lynwood, Silverado, and Sunnyside (2 deepest zones), with depths ranging from 236 to 1,480 feet BGS. Norwalk #2 is the third key well representing the Montebello Forebay and is at the southern margin of the Forebay where it transitions into the Central Basin Pressure Area. Unlike Rio Hondo #1 and Pico #2, water level responses are less pronounced in response to the seasonal discharge and recharge influences, with seasonal swings of around 20 feet compared to the over 30-foot seasonal swings at Rio Hondo #1 and Pico #2. Groundwater elevations are deepest in Zone 3, the Silverado Aquifer, suggesting that this aquifer is the most heavily pumped in the area. The water level in Zone 3 increased by about 13 feet over the past WY. Water levels in Norwalk #2 are the highest levels recorded in the past three years.

2.5 GROUNDWATER LEVELS IN THE LOS ANGELES FOREBAY

Figure 2.6 is the key hydrograph for WRD's Huntington Park #1 nested monitoring well located in the Los Angeles Forebay near the intersection of Slauson Avenue and Alameda Street. There are five individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Gaspur, Exposition, Gage, Jefferson, and Silverado, with depths ranging from 114 to 910 feet BGS. Only four of the zones are shown on the hydrograph because the shallowest well (screened from 114 to 134 feet BGS in Gaspur Aquifer sediments) is dry and perforated above the water table, and therefore no water elevations are shown on the graph. There is a large separation in water levels between Zone 4 and the three deeper zones, suggesting the presence of a low permeability aquitard(s) above Zone 3 that hydraulically isolates the Exposition Aquifer from the deeper aquifers. Water levels in the deepest two zones, the Jefferson and Silverado Aquifers, are generally similar. Water levels in the Jefferson Aquifer decreased by about 2.5 feet and in the Silverado Aquifer they decreased by about 2 feet over the past WY. Unlike recent decreases over the past 6 years in the Montebello Forebay, water levels in the Los Angeles Forebay have remained relatively stable over the past 17 years.

2.6 GROUNDWATER LEVELS IN THE CENTRAL BASIN PRESSURE AREA

Figure 2.7 is a hydrograph for WRD's South Gate #1 nested monitoring well, which is located in the north-central portion of the Central Basin Pressure Area, just outside the Montebello and Los Angeles Forebays. There are five individual wells (zones) that are screened, from shallowest to deepest, in the Exposition, Lynwood, Silverado, and Sunnyside Aquifers; and the Pico Formation, with depths ranging from 220 to 1,460 feet BGS. Water levels in Zones 1 through 4 generally behave similarly in response to seasonal discharge and recharge. The upper zone has much shallower water levels, shows little seasonal response, and is isolated from the aquifers below by an aquitard, resulting in the observed hydraulic separation. South Gate #1 water levels increased by about 7 feet in the deeper aquifers over WY 2016-17, and have generally declined by as much as 17 feet over the past 17 years.

Figure 2.8 is a hydrograph for WRD's Willowbrook #1 nested monitoring well, which is located in the Central Basin Pressure Area, about 7 miles down-gradient of the Montebello Forebay. There are four individual wells (zones) that are screened, from shallowest to deepest, in the Gage, Lynwood, Silverado, and Sunnyside Aquifers, with depths ranging from 200 to 905 feet BGS. Zone 1 is screened in the deepest responding aquifer. The upper three zones have generally shallower water levels than Zone 1. Zones 3 and 4 track very closely. These trends suggest some hydraulic separation (aquitards) between Zones 1 and 2, and between Zones 2 and 3. Zones 3 and 4, have little hydraulic separation. Water levels have increased about 3 feet in Zone 1 and about 0.5 foot in Zone 2 over WY 2016-17. Water levels in Zones 3 and 4 have increased by slightly less than 0.5-foot over the past WY. Water levels in Willowbrook #1 have generally declined over the past 18 years.

Figure 2.9 is a hydrograph for key nested monitoring well Long Beach #6 located in the southern portion of the Central Basin Pressure Area. There are six individual wells (zones) that are screened in the following (from shallowest to deepest): Gage, Lynwood, Silverado, and Sunnyside (two zones) Aquifers, and Pico Formation with depths ranging

from 220 to 1,510 feet BGS. Because this portion of the Central Basin Pressure Area has multiple confined aquifers separated by substantial aquitards, and experiences heavy local seasonal pumping cycles, water level fluctuations can be larger than in other areas. For example, water levels in Zones 4 and 5 are the deepest responders; they are screened in the Lynwood and Silverado Aquifers, rise and fall more than 100 feet through typical seasonal cycles, and occur at elevations ranging from highs at near sea level to lows greater than 120 feet below sea level. Water levels in the other zones also generally show significant seasonal variation. **Figure 2.9** shows minor decreases to slight increases in water levels in Zones 1, 2, 3, and 6 over the past WY; water levels in Zones 4 and 5 have increased about 5 feet from the previous WY.

Seal Beach #1 is included as a key nested monitoring well for the Central Basin Pressure Area due to its proximity inland of the Alamitos Gap Seawater Intrusion Barrier Recycled Water Project. Historical groundwater elevations for Seal Beach #1 are shown on **Figure 2.10**. There are seven individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Gaspur, Gage, Lynwood, Silverado, and Sunnyside (3 zones), with depths ranging from 60 to 1,365 feet BGS. Zone 4, screened in the Silverado aquifer, is the deepest responding unit at Seal Beach #1. Zone 5 responds similarly to Zone 4, but draws down less during heavily pumped periods. Zones 1, 2, and 3 overlay on the hydrograph and have had a relatively muted seasonal response over the past couple of years. Zones 6 and 7 show a smaller seasonal response than the five lower zones, with groundwater elevations at or slightly below sea level, suggesting partial isolation from the lower aquifer systems. Groundwater levels in Zone 4 increased about 25 feet over WY 2016-17.

2.7 GROUNDWATER LEVELS IN THE WHITTIER AREA

The Whittier Area of the Central Basin extends from the Puente Hills south and southwest to the Santa Fe Springs-Coyote Hills uplift. The western boundary is an arbitrary line separating the Whittier Area from the Montebello Forebay and the eastern boundary is the Orange County line. **Figure 2.11** is a hydrograph from WRD's Whittier #1 nested

monitoring well located in the eastern part of the Whittier Area. There are five individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Gage, Lynwood, Silverado, and Sunnyside (2 zones), with depths ranging from 200 to 1,200 feet BGS. Groundwater levels in the Whittier Area do not show a seasonal fluctuation typical of other areas of the Central Basin and adjacent Montebello Forebay Area, which suggests limited groundwater discharge and recharge. Zones 1 through 4 have similar groundwater elevations and track very closely over time while the Zone 5 groundwater elevation is over 80 feet higher suggesting substantial isolation by an aquitard(s). The Whittier #1 hydrograph indicates that groundwater levels in the Whittier Area have decreased about 1 foot over the past WY and have decreased 10 to 12 feet over the past 17 years.

2.8 GROUNDWATER LEVELS IN THE WEST COAST BASIN

Figure 2.12 is a hydrograph for WRD's PM-4 Mariner nested monitoring well, which is located in the City of Torrance, in the coastal area inland from the West Coast Basin Seawater Intrusion Barrier. There are four individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Lynwood (2 zones), Silverado, and Sunnyside, with depths ranging from 200 to 710 feet BGS. All four zones respond similarly to seasonal fluctuations. Water levels in Zone 1 (Sunnyside) are deepest, separated from Zone 2 (Silverado) which is several feet higher. Water levels in Zones 3 and 4 (Lynwood and Gage) are both about 2 feet above those in Zone 2. Water levels have increased between 0.5 and 2 feet at PM-4 Mariner in WY 2016-17 and have increased as much as 8 feet over the past 19 years.

Figure 2.13 is a hydrograph for WRD's Carson #1 nested monitoring well, which is located in the inland region of the West Coast Basin. There are four individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Gage, Lynwood, Silverado, and Sunnyside, with depths ranging from 250 to 1,110 feet BGS. Water levels in Zone 1 track very similar to Zone 2 throughout the year and are the deep responding aquifers at this location. Zone 3 tracks similar to Zone 4. Groundwater elevations currently

differ by about 35 feet between the upper two and lower two zones, which suggests the presence of a low permeability aquitard(s) between them that hydraulically isolate the shallow aquifers from the deeper ones. Water levels in Zones 1 and 2 both have decreased about 1 foot over the past WY, but have generally increased 28 feet over the past 18 years.

Manhattan Beach #1 is a relatively newer WRD nested monitoring well (constructed in 2011) and was designated as a key nested monitoring well for the West Coast Basin due to its proximity one half mile inland of the West Coast Basin Seawater Intrusion Barrier. **Figure 2.14** is a hydrograph for Manhattan Beach #1, which includes seven individual wells (zones) that are screened in the following aquifers (from shallowest to deepest): Gage, Lynwood, Silverado (2 zones), Sunnyside, and Pico Formation (2 zones), with depths ranging from 180 to 1,990 feet BGS. Zone 3 is screened in the Sunnyside Aquifer and has the deepest groundwater levels, up to 30 feet lower than Zones 1, 2, 4, and 5 which generally track together. Water levels in Zones 6 and 7 are six to eight feet above Zones 1, 2, 4, and 5. Seasonal fluctuations are not pronounced at the Manhattan Beach #1 location and groundwater levels did not change significantly over the past water year, however water levels in Zone 3 have increased about 2 feet over the past WY and about 8 feet since this well was installed.

Figure 2.15 is a hydrograph for WRD's Wilmington #2 nested monitoring well, which is located in the West Coast Basin, inland of the Dominguez Gap Seawater Intrusion Barrier. There are five individual wells (zones) that are screened, from shallowest to deepest, in the Gage, Lynwood (2 zones), Silverado, and Sunnyside Aquifers with depths ranging from 120 to 970 feet BGS. Water levels in Zones 1 through 4 are generally deeper and behave similarly in response to seasonal influences. The upper zone has shallower water levels, and shows less seasonal change suggesting hydraulic separation from the lower 4 zones. Wilmington #2 water levels have increased by about 1.0 to 2.5 feet in the deeper aquifers over WY 2016-17, and have increased by as much as 24 feet over the past 19 years.

SECTION 3
GROUNDWATER AND REPLENISHMENT WATER QUALITY

This section discusses the vertical and horizontal distribution of water quality constituents in the CBWCB based on data from WRD's nested monitoring wells, purveyors' production wells, and source waters used for CBWCB groundwater replenishment. Regional groundwater quality maps included herein depict constituents of interest to WRD and District stakeholders in the nested monitoring wells and production wells where water quality data is available.

Comparison of water quality results to various regulatory standards are made throughout this section. A brief discussion describing the regulatory standards used in the report follows. A Primary Maximum Contaminant Level (MCL) is an enforceable drinking water standard that the California Environmental Protection Agency State Water Resources Control Board, Division of Drinking Water (DDW) establishes after health effects, risk assessment, detection capability, treatability, and economic feasibility are considered. A Secondary Maximum Contaminant Level (SMCL) is established for constituents that impact aesthetics of the water, such as taste, odor, and color, but do not impact health. Various other criteria are used in discussing water quality. A Public Health Goal (PHG) is an advisory level that is developed by the Office of Environmental Health Hazard Assessment (OEHHA) after a thorough review of health effects and risk assessment studies. A Notification Level (NL) and Response Level (RL) are non-enforceable health-based advisory levels established by the DDW based on preliminary reviews of health effects studies for which enforceable levels have not been established. NLs and RLs replaced State Action Levels effective January 1, 2005 per California Health and Safety Code Section 116455. It should also be noted that constituents with NLs often are considered unregulated contaminants for which additional monitoring may be required to determine the extent of exposure before MCLs and/or PHGs are established.

3.1 QUALITY OF GROUNDWATER

The focus of this section is groundwater quality from samples collected from WRD nested monitoring wells and purveyors' production wells. Section 1 of this report described the value of data from aquifer-specific nested monitoring wells and these data provide the most valuable insight into CBWCB groundwater quality. Semi-annual groundwater samples from WRD nested wells were collected and submitted to a State-certified laboratory for analytical testing for general water quality constituents and known or suspected natural and man-made contaminants. **Table 3.1** presents water quality analytical results from WRD nested monitoring wells in the Central Basin during WY 2016-17. **Table 3.2** presents water quality analytical results from WRD nested monitoring wells in the West Coast Basin during WY 2016-17. Complementing the data from the nested monitoring well network, data for CBWCB production wells were obtained from the DDW based on results submitted over the past three years by purveyors for their DDW Title 22 drinking water compliance.

Water quality maps for nested monitoring wells and production wells are presented herein for 12 water quality constituents (**Figures 3.1 – 3.24**). The 12 constituents include total dissolved solids (TDS), iron, manganese, chloride, nitrate, trichloroethylene (TCE), tetrachloroethylene (PCE), arsenic, perchlorate, hexavalent chromium, 1,4-Dioxane, and tertiary butyl alcohol (TBA). The maps illustrate areal and vertical differences in water quality and compare the aquifer-specific water quality data from WRDs nested monitoring wells to the averaged water quality data collected from purveyors' production wells.

3.1.1 Total Dissolved Solids (TDS)

TDS is a measure of the total mineralization of water and is indicative of general water quality. In general, the higher the TDS, the less desirable a given water supply is for beneficial uses. The SMCL for TDS ranges from 500 milligrams per liter (mg/L), which is the recommended level, to an upper level of 1,000 mg/L, and to 1,500 mg/L, which is the level allowed for short-term use. WRD uses the 1,000 mg/L upper level SMCL for water quality comparisons and analyses.

WRD nested monitoring well data for WY 2016-17 indicate relatively low TDS concentrations for groundwater in the producing aquifers of the Central Basin (**Figure 3.1**). In the Central Basin, 30 out of 33 (91%) WRD nested monitoring wells screened in the Silverado Aquifer had TDS concentrations below the SMCL of 1,000 mg/L and 25 out of 33 (76%) were below 500 mg/L. In contrast, West Coast Basin nested monitoring well data show generally higher TDS concentrations with just 12 out of 22 (55%) nested wells screened in the Silverado Aquifer having TDS concentrations below 1,000 mg/L, and 8 out of 22 (36%) wells below 500 mg/L. Elevated TDS concentrations in the West Coast Basin were observed along the coast from Redondo Beach to Los Angeles International Airport (LAX), in the Inglewood area, and the Dominguez Gap area.

Figure 3.2 presents DDW water quality data for TDS in production wells across the WRD service area for the period spanning WYs 2014-17. In the Central Basin, TDS was not detected above the Upper Level SMCL of 1,000 mg/L in any of the 224 production wells sampled for TDS during this period, and 164 of those wells (73%) had TDS concentrations below 500 mg/L.

West Coast Basin production well data indicate that most drinking water wells had TDS concentrations below 1000 mg/L. TDS was detected below the Upper Level SMCL in 25 out of 28 production wells (89%) sampled for TDS during this period. Fifteen production wells (54%) were below 500 mg/L. Production wells with higher levels of TDS are generally located near the coast within the West Coast Basin, while further inland production wells generally had lower TDS concentrations. The elevated TDS levels may be caused by seawater intrusion, connate brines, or possibly oil field brines.

3.1.2 Iron

Iron occurs naturally in groundwater. Sources for iron in the water supply are both natural and man-made. Iron is leached from sediments in subsurface aquifers and steel pipes used for construction of water wells and distribution systems. Sufficient concentrations of iron in water can affect its suitability for domestic or industrial purposes. Some industrial

processes cannot tolerate more than 0.1 mg/L iron. The SMCL for iron in drinking water is 0.3 mg/L. High concentrations of iron in water can stain plumbing fixtures and clothing, encrust well screens, clog pipes, and may impart a salty taste. While these problems are recognized, iron is considered an essential nutrient, important for human health, and does not pose significant health effects except in special cases.

Nested monitoring well data do not indicate iron to be a widespread water quality problem in groundwater in the WRD service area. **Figure 3.3** shows iron data in WRD nested monitoring well locations for WY 2016-17. In the Central Basin, iron was detected in 29 of 33 (88%) nested well locations. Iron was detected in concentrations above the MCL at 8 of those 29 locations; however it was only detected at concentrations above the SMCL in Silverado zones at 3 nested well locations.

In the West Coast Basin, iron was detected in the Silverado zones in 20 out of 22 nested well locations (91%). Eleven nested well locations had iron concentrations above the SMCL, four of those were detected in Silverado Zones.

Figure 3.4 presents DDW water quality data for iron in production wells across the WRD service area for the period spanning WYs 2014-17. In the Central Basin, 164 of 224 (73%) production wells have iron concentrations in groundwater that are below the SMCL. In the West Coast Basin, 11 production wells out of 28 (39%) have iron concentrations below the SMCL.

3.1.3 Manganese

Manganese is naturally-occurring and is objectionable in water in the same manner as is iron. Stains caused by manganese are black and are more unsightly and harder to remove than those caused by iron. While manganese is considered an essential nutrient for human health at low levels, an SMCL of 50 micrograms per liter (µg/L) is established for manganese due to its undesirable aesthetic qualities.

Manganese concentrations in the WRD nested monitoring wells (**Figure 3.5**) exhibit widespread vertical and horizontal variations across the WRD service area. In the southern portion of the Central Basin, elevated manganese typically occurs in shallower aquifers above the Silverado producing zones. In the northern portion of the Central Basin, manganese is present in shallow zones, the Silverado zones, and the deeper zones. Eight out of 33 (24%) nested monitoring well locations in the Central Basin had a zone with manganese concentrations exceeding the SMCL in the Silverado Aquifer. In the West Coast Basin, manganese was detected above the SMCL in the Silverado zones at 13 out of 22 (59%) nested well locations.

Figure 3.6 presents DDW water quality data for manganese in production wells across the WRD service area for the period spanning WYs 2014-17. In the Central Basin, data show a number of wells having elevated manganese concentrations, but 190 out of 227 production wells (84%) had concentrations below the SMCL. The production wells with elevated manganese levels are not limited to a specific area and tend to be widespread. There does appear to be an area around and south of the Montebello Forebay Spreading Grounds and a second area at the southern end of the Central Basin where manganese is consistently below the SMCL or not detected at all. In the West Coast Basin, 10 out of 28 production wells (36%) had concentrations of manganese below the SMCL.

3.1.4 Chloride

Chloride at elevated levels causes water to taste salty and it is the characteristic constituent used to identify seawater intrusion. The recommended SMCL for chloride is 250 mg/L with an upper SMCL of 500 mg/L, and a short term SMCL of 600 mg/l.

Figure 3.7 presents water quality data for chloride in WRD nested monitoring wells in the WRD service area during WY 2016-17. In the Central Basin, all 33 nested monitoring well locations generally have low chloride concentrations. No Central Basin zone in the Silverado Aquifer exceeded the upper level SMCL. In the West Coast Basin, chloride concentrations exceeded the upper SMCL limit in the Silverado zones in 8 of the 22 (36%) nested well locations, primarily in areas where seawater intrusion could be the source, or

from sources yet to be identified. Eleven nested wells in the West Coast Basin show chloride impacts above the MCL in non-Silverado Zones.

Figure 3.8 presents DDW water quality data for chloride in production wells in the WRD service area for the period spanning WYs 2014-17. Chloride was not detected above the SMCL in any of the 224 Central Basin production wells sampled for chloride during this period. In the West Coast Basin, two of the 28 production wells tested, both located on the west side of the basin, had chloride concentrations above the upper SMCL.

3.1.5 Nitrate

MCLs were established by DDW for two forms of nitrogen in drinking water, nitrate and nitrite. Nitrate (measured as Nitrate) has an MCL of 45 mg/L, which corresponds to 10 mg/L of nitrate as nitrogen. Nitrite (measured as nitrogen) has an MCL of 1 mg/L. The combined total of the nitrate and nitrite, measured as total nitrogen, has an MCL of 10 mg/L. These constituents are regulated because they present possible acute health risks and can cause anoxia in infants. When consumed in excess of the MCLs, they reduce the uptake of oxygen causing shortness of breath, lethargy, and a bluish skin color.

Nitrate concentrations in groundwater are also a concern because their presence indicates that a degree of contamination has occurred due to the degradation of organic matter. Native groundwater typically does not contain nitrate. It can be introduced into groundwater from agricultural practices such as fertilization of crops or lawns and leaching of animal wastes. Low concentrations of nitrogen compounds, including nitrate and nitrite, are present in treated recycled water below regulatory and permitted limits and may be a source of nitrate loading to groundwater. Typically, organic nitrogen and ammonia are the initial byproducts of the decomposition of human or animal wastes. Upon oxidation, the organic nitrogen and ammonia are converted first to nitrite and then nitrate ions in the subsurface. A portion of the nitrate and nitrite are converted to nitrogen gas and are returned to the atmosphere.

Figure 3.9 presents nitrate (as nitrogen) water quality data for nested monitoring wells in

the WRD service area during WY 2016-17. In the Central Basin, nitrate does not exceed the MCL in the Silverado zone of any nested monitoring well location. Nitrate detections above the MCL were limited to the shallowest zones at 2 of the 33 (6%) nested well locations. Nested monitoring wells in the immediate vicinity of the Montebello and Los Angeles Forebays typically contain nitrate at concentrations below the MCL in upper zones. Some wells downgradient from the Montebello Forebay have middle zones with nitrate detections below the MCL. Nested wells further downgradient from the forebays generally do not have detectable concentrations of nitrate. The detectable but relatively low concentrations of nitrate at and near the forebays may be due to the use of local water and/or recycled water for groundwater recharge at the spreading grounds. The generally widespread shallow occurrences of nitrate throughout the Central Basin may be attributed to local surface recharge impacted by historical agricultural activities, but also could be associated with industrial operations.

In the West Coast Basin nested monitoring wells, nitrate was present above the MCL in the shallowest zones of 2 out of the 22 (9%) nested monitoring well locations. In one of those two nested monitoring wells, the nitrate was detected above the MCL in a Silverado aquifer zone. Similar to the Central Basin, shallow occurrences of nitrate in the West Coast Basin may be attributable to local surface recharge impacted by agricultural activities prior to extensive land development.

Figure 3.10 presents DDW water quality data for nitrate in production wells across the WRD service area for the period spanning WYs 2014-17. One Central Basin production well, located in the Los Angeles Forebay, contained nitrate above the MCL. The nitrate MCL was not exceeded in any production well in the West Coast Basin during WYs 2014-17.

3.1.6 Trichloroethylene (TCE)

TCE is a solvent used in metal degreasing, textile processing, and dry cleaning. In addition to multiple acute health effects, TCE is also classified as a probable human carcinogen. The MCL for TCE in drinking water is 5 µg/L. If present in water, it can be removed easily

by common treatment processes, including air stripping or vapor extraction utilizing granular activated carbon filtration media.

TCE (**Figure 3.11**) was not detected in 23 out of 33 (70%) WRD nested monitoring well locations in the Central Basin. Of the 10 nested wells where TCE was detected in the Central Basin, three locations had TCE above the MCL. One of the 10 nested wells had a detectable TCE concentration in a Silverado Aquifer Zone, however it was detected at a concentration below the MCL. In the West Coast Basin, TCE was not detected in 20 out of 22 (91%) nested monitoring wells. Of the 2 nested wells where TCE was detected in the West Coast Basin, one location had TCE above the MCL. No nested well in the West Coast Basin had a detectable TCE concentration in a Silverado Aquifer zone.

Figure 3.12 presents DDW water quality data for TCE in production wells across the WRD service area for the period spanning WYs 2014-17. In the Central Basin, TCE was not detected in 179 of 234 (76%) of the production wells that were tested. Of the 55 production wells that had detectable TCE levels, 20 wells had concentrations above the MCL. Wells impacted by TCE are generally located in the northern portion of the Central Basin, within or near the Montebello and Los Angeles Forebays. In the West Coast Basin, TCE was detected at a concentration below the MCL in one West Coast Basin production well during WYs 2014-17.

3.1.7 Tetrachloroethylene (PCE)

PCE (also known as tetrachloroethylene, perc, perclene, and perchlor) is a solvent used commonly in the dry cleaning industry, as well as in metal degreasing and textile processing. Like TCE, PCE is a probable human carcinogen. The MCL for PCE in drinking water is 5 µg/L. Like TCE, PCE is readily removed from water using common treatment processes.

During WY 2016-17, PCE (**Figure 3.13**) was not detected at 22 out of 33 (67%) nested well locations in the Central Basin. Of the 11 nested wells where PCE was detected in the Central Basin, three were detected within a Silverado Aquifer zone at concentrations below

the MCL. PCE was detected in two nested wells at concentrations above the MCL; however neither of those detections were in a Silverado Aquifer zone. In the West Coast Basin, PCE was detected at one nested well at a concentration below the MCL. PCE was not detected in any Silverado Aquifer zone in the West Coast Basin during WY 2016-17.

Figure 3.14 presents DDW water quality data for PCE in production wells across the WRD service area for WYs 2014-17. In the Central Basin, PCE was not detected in 181 out of the 234 (77%) production wells that were tested. Of the 53 production wells that had detectable PCE levels, 14 wells had concentrations above the MCL. Production wells with detectable PCE concentrations are primarily located within the vicinity of the Los Angeles and Montebello Forebays and extend southwestward and southward into the Central Basin Pressure Area. PCE was not detected in any of the West Coast Basin production wells.

3.1.8 Arsenic

Arsenic is an element that occurs naturally in the earth's crust and accordingly there are natural sources of arsenic, including weathering and erosion of rocks, deposition of arsenic in water bodies, and uptake of the metal by animals and plants. Consumption of food and water are the major sources of arsenic exposure for the majority of U.S. citizens. Over 90% of commercial arsenic is used as a wood preservative in the form of chromate copper arsenate to prevent dry rot, fungi, molds, termites, and other pests. People may also be exposed from industrial applications, such as semiconductor manufacturing, petroleum refining, animal feed additives, and herbicides. Arsenic is classified as a known human carcinogen by the United States Environmental Protection Agency (USEPA), and also causes other health effects, such as high blood pressure and diabetes. The DDW established an MCL of 10 µg/L for arsenic.

Figure 3.15 presents water quality data for arsenic in WRD nested monitoring wells during WY 2016-17. Arsenic concentrations greater than the MCL in the Central Basin were detected at 8 out of 33 (24%) nested well locations; two of those eight wells had arsenic concentrations that exceeded the MCL in a Silverado Aquifer zone. In the West Coast Basin, arsenic was detected above the MCL at 4 out of 22 (18%) nested monitoring well

locations, two of those detections above the MCL were in a Silverado Aquifer zone.

Figure 3.16 presents DDW water quality data for arsenic in production wells across the WRD service area for the period spanning WYs 2014-17. In the Central Basin, 8 out of 223 (4%) production wells have arsenic concentrations above the MCL. Arsenic did not exceed the MCL in any of the West Coast Basin production wells.

3.1.9 Perchlorate

Perchlorate is used in a variety of defense and industrial applications, such as rockets, missiles, road flares, fireworks, air bag inflators, lubricating oils, tanning and finishing leather, and the production of paints and enamels. Under certain conditions, perchlorate is also reported to occur naturally in groundwater (Trumpolt, 1995). When ingested, it can inhibit the proper uptake of iodide by the thyroid gland, which causes a decrease in hormones for normal growth and development and normal metabolism. In October 2007, the DDW established an MCL of 6 µg/L for perchlorate.

Figure 3.17 presents perchlorate water quality data for WRD nested monitoring wells during WY 2016-17. In the Central Basin, perchlorate was detected at 17 out of 33 (52%) nested monitoring well locations; eight of these detections were in a Silverado Aquifer zone, all below the MCL. In the West Coast Basin, perchlorate was detected in six out of 22 (27%) nested monitoring wells, with one nested well containing a concentration above the MCL. Perchlorate was detected at a concentration below the MCL in one of the West Coast Basin nested monitoring wells in the Silverado Aquifer zone.

Figure 3.18 presents DDW water quality data for perchlorate in production wells across the WRD service area for the period spanning WYs 2014-17. In the Central Basin, 6 out of 226 (3%) production wells had detectable perchlorate, with two production wells testing for perchlorate above the MCL. Perchlorate was not detected in any of the West Coast Basin production wells.

3.1.10 Hexavalent Chromium

Hexavalent chromium (chromium-6) and trivalent chromium (chromium-3) are two forms of the metal chromium found in groundwater. Together, these two forms of chromium are designated "total chromium". The MCL for total chromium is 50 µg/L. In 2014 California established an MCL of 10 µg/L for hexavalent chromium; however, on May 31, 2017, a judgement was issued by the Superior Court of California that invalidated the MCL for hexavalent chromium in drinking water. The Court has ordered the SWRCB to adopt a new MCL; in the meantime the MCL for Total Chromium will remain in place The SWRCB will use data collected since the standard was adopted in 2014 to help establish a new MCL; they note that it generally takes between 18 and 24 months to develop regulation. To remain consistent with prior reporting and aid in assessing concentration trends, WRD will continue to discuss hexavalent chromium results in the text and associated Figures below in terms of the historic MCL value of 10 µg/L until a new MCL is established by the SWRCB.

Both forms of chromium occur naturally in groundwater and are also introduced to soil and groundwater through disposal practices from commercial and industrial operations. Only hexavalent chromium is considered to pose health risks. It has been known to increase cancer risk when inhaled and recently shown to increase cancer risk if ingested.

Figure 3.19 shows hexavalent chromium concentrations in WRD nested monitoring wells in the WRD service area. In the Central Basin hexavalent chromium was detected in 32 out of 33 (97%) nested well locations. Only two nested well locations had hexavalent chromium above a concentration of 10 µg/L and neither were in a Silverado Aquifer zone. In the West Coast Basin, hexavalent chromium was not detected above a concentration of 10 µg/L at any nested well location. Hexavalent chromium was detected below 10 µg/L at 21 out of 22 (95%) nested monitoring well locations.

Figure 3.20 shows hexavalent chromium in WRD service area production wells from sampling conducted during WYs 2014-17. In the Central Basin, hexavalent chromium was not detected in 164 of the 213 (77%) production wells that were tested. Of the 67 Central

Basin production wells that had detectable hexavalent chromium levels, none had concentrations above 10 µg/L. Hexavalent chromium was not detected in any of the 22 production wells tested in the West Coast Basin.

3.1.11 1,4-Dioxane

1,4-Dioxane is a synthetic organic compound. It is used as a stabilizer for solvents (in particular 1,1,1-trichloroethane) and as a solvent itself in a number of industrial and commercial applications. 1,4-Dioxane is also found in trace amounts in some cosmetic and personal care products such as detergents and shampoos. 1,4-Dioxane is highly soluble in water, does not readily bind to soils, readily leaches to groundwater, and is resistant to naturally occurring biodegradation processes. EPA classifies 1,4-dioxane as a probable human carcinogen and a known irritant, and as a result it is included in the Third Unregulated Contaminant Monitoring Rule (UCMR 3). In November 2010 the State Water Resources Control Board (SWRCB) established a drinking water notification level (NL) of 1 µg/L for 1,4-Dioxane.

Figure 3.21 shows 1,4-Dioxane concentrations in WRD nested monitoring wells in the WRD service area. Testing for 1,4-Dioxane was conducted at 32 of 33 nested well locations in the Central Basin during WY 2016-17. 1,4-Dioxane was not detected in 18 of 32 (56%) nested well locations. Of the 14 nested wells where 1,4-Dioxane was detected, 7 were found in Silverado Aquifer zones; all detections were at concentrations greater than the NL. In the West Coast Basin, testing for 1,4-Dioxane was conducted at 18 of 22 nested well locations. 1-4 Dioxane was detected at 1 of 18 (6%) nested wells locations in a non-Silverado Aquifer zone. 1,4-Dioxane was not detected at or above the Response Level of 35 µg/L in any of the nested well locations.

Figure 3.22 shows 1,4-Dioxane in WRD service area production wells from sampling conducted during WYs 2014-17. In the Central Basin 1,4-Dioxane was detected in 79 of the 107 (74%) production wells that were tested. In the West Coast Basin, testing for 1,4-Dioxane was only conducted on 4 production wells. 1,4-Dioxane was not detected in any of those production wells. 1,4-Dioxane was not detected at or above the Response Level

of 35 µg/L in any of the production wells tested.

3.1.12 Tertiary Butyl Alcohol (TBA)

Tertiary butyl alcohol (TBA) is fuel oxygenate and breakdown by-product of methyl tert-butyl ether (MTBE). TBA is quite mobile in groundwater and is resistant to degradation. Exposure to TBA can lead to irritation of the mucous membranes, nausea, defatting of the skin, and intoxication. TBA is believed to be a potential carcinogen. Currently there is no Federal drinking water standard for TBA, although California has established a drinking water notification level (NL) of 12 µg/L.

Figure 3.23 shows TBA concentrations in WRD nested monitoring wells in the WRD service area. In the Central Basin TBA was not detected in 31 out of 33 (94%) nested well locations. In the two locations where TBA was detected, only one of those contained TBA at a concentration above the NL, and neither of the detections were found in a Silverado Aquifer zone. In the West Coast Basin, TBA was detected in 3 of 22 (14%) nested well locations; two of these detections were at concentrations above the NL, and one of those was detected in a Silverado Aquifer zone.

Figure 3.24 shows TBA in WRD service area production wells from sampling conducted during WYs 2014-17. In the Central Basin, only 3 production wells were tested for TBA; it was not detected in any of those wells. In the West Coast Basin, testing for TBA was conducted on 6 production wells; it was only detected in one of those wells, at a concentration lower than the NL.

3.2 QUALITY OF REPLENISHMENT WATER

This section discusses water quality data for key water quality constituents in CBWCB replenishment water and local surface water. Although numerous constituents are monitored, the constituents discussed and reported here are the ones found to be most prevalent at elevated levels or are of current regulatory interest. The data are classified according to their sources. The key water quality parameters of this discussion were also discussed for the WRD nested monitoring wells: TDS, iron, manganese, chloride, nitrate,

TCE, PCE, arsenic, perchlorate, and hexavalent chromium. Monitoring of these constituents helps to understand the general chemical nature of the recharge source, and its suitability for replenishing the groundwater basins.

3.2.1 Quality of Imported Water

Surface water is imported by the Metropolitan Water District of Southern California (MWD) to the WRD service area from the Colorado River and from Northern California via the State Water Project for potable supply and for groundwater recharge. Colorado River water deliveries have been suspended due to the presence of quagga mussels; however, 32,693 AF of State Water Project water was received for replenishment in 2016-17. Currently, treated imported water and advanced treated recycled water are injected into the three seawater intrusion barriers. Treated imported water meets all drinking water standards and thus, is suitable for direct injection. Untreated imported water, when available, is used for recharge at the Montebello Forebay Spreading Grounds. Average water quality data for treated and untreated imported water are presented in **Table 3.3**

In 2016, the average TDS concentration of untreated Colorado River water was 630 mg/L and the average TDS concentration of untreated water from the State Water Project was 180 mg/L. Only untreated State Water Project water was received for recharge in the Montebello Forebay spreading grounds in 2016.

In 2016, average concentrations of nitrate (as nitrogen) were below detection limits in untreated Colorado River water and the average nitrate concentration in water from the untreated State Water Project was 0.8 mg/L. Recently and historically, both Colorado River and State Water Project nitrate concentrations have remained below the MCL.

In 2016, the average iron and manganese concentrations in untreated Colorado River water and State Water Project water were below detection limits. Both Colorado River and State Water Project iron and manganese concentrations have recently and historically been below the SMCL.

The average chloride concentrations in water from the Colorado River and State Water Project have not changed significantly over the past several years. State Water Project and Colorado River chloride concentrations have historically been below the SMCL of 500 mg/L for chloride.

According to the MWD, TCE, PCE, and perchlorate have not been detected in water from the Colorado River or State Water Project during calendar year 2016. Hexavalent chromium was not detected in water from the Colorado River; however it was detected at a concentration of 1.0 µg/L in water from the State Water Project. Both Colorado River and State Water Project hexavalent chromium concentrations have recently and historically been below the historical MCL of 10 µg/L.

3.2.2 Quality of Recycled Water

Recycled water is used for groundwater recharge in the WRD Service Area for percolation through the Montebello Forebay spreading grounds, which is comprised of the Rio Hondo Coastal Spreading Grounds and the San Gabriel Coastal Spreading Grounds, and for injection into the seawater barriers. In the Montebello Forebay, tertiary-treated recycled water produced by the County Sanitation Districts of Los Angeles County (CSDLAC) at their Whittier Narrows Water Reclamation Plant (WRP), San Jose Creek East WRP, San Jose Creek West WRP, and Pomona WRP facilities is diverted into the Montebello Forebay spreading grounds where it percolates into the subsurface to recharge underlying aquifers. The effluent from these WRPs is carefully controlled and monitored, as required by permits and other regulations, and typically shows little water quality variation over time. Average water quality data for the effluent from these WRPs is shown in **Table 3.3**. All constituents listed have remained stable over recent WYs. Furthermore, arsenic, TCE, PCE, perchlorate, and hexavalent chromium have either not been detected or have been detected well below their respective MCLs in recycled water from the four WRPs. 1,4-Dioxane concentrations in recycled water from the Whittier Narrows, San Jose Creek West, and Pomona WRPs are all below the NL; however, recycled water from the San Jose Creek East WRP has an average concentration of 1,4-Dioxane (1.1 µg/L) that slightly exceeds the NL of 1.0 µg/L. N-nitrosodimethylamine (NDMA) has been detected above its NL of 10 µg/L in recycled

water from the Whittier Narrows, San Jose Creek West, San Jose Creek East, and Pomona WRPs.

Currently, both treated imported water and advanced treated recycled water produced by the West Basin Municipal Water District (WBMWD) Edward C. Little Water Recycling Facility (ELWRF) are injected at the West Coast Basin Barrier to prevent the intrusion of seawater and replenish the groundwater basin. Treatment processes at the ELWRF includes microfiltration, reverse osmosis, ultraviolet light, advanced oxidation with hydrogen peroxide, and chemical stabilization. The advanced treated recycled water complies with all drinking water standards and thus, is suitable for direct injection. The ELWRF was expanded in September 2013 and it is expected that advanced treated recycled water will replace nearly all of the imported water used for injection at the West Coast Basin Barrier. **Table 3.3** presents average water quality data for the advanced treated recycled water produced by the ELWRF.

The Alamitos Gap Seawater Intrusion Barrier currently receives both treated imported water and advanced treated recycled water produced by WRD's Leo J. Vander Lans Advanced Water Treatment Facility (Vander Lans AWTF) for injection. The Vander Lans AWTF treats disinfected tertiary effluent from the CSDLAC Long Beach Water Reclamation Plant using microfiltration, reverse osmosis, ultraviolet light, and advanced oxidation using hydrogen peroxide. The advanced treated recycled water meets drinking water quality standards and other stringent regulations for direct injection into the aquifers. The Vander Lans AWTF was expanded in 2014 to allow additional capacity and to replace nearly all of the imported water used for injection at the Alamitos Gap Seawater Intrusion Barrier. **Table 3.3** presents average water quality data for the advanced treated recycled water produced by the Vander Lans AWTF.

The City of Los Angeles Terminal Island Water Reclamation Plant/Advanced Water Treatment Facility (TIWRP) produces advanced treated recycled water using microfiltration, reverse osmosis, and disinfection with chlorine. This water meets drinking water quality standards and other stringent regulations for direct injection into aquifers.

N-nitrosodimethylamine (NDMA) has been detected above its NL of 10 µg/L in recycled water from the TIWRP. Currently treated imported water is blended with advanced treated recycled water from the TIWRP for injection at the Dominguez Gap Seawater Intrusion Barrier (DGSIB). Expansion of the TIWRP was completed in December 2016 and included the installation of an advanced oxidation process into the treatment train. It is anticipated that advanced treated recycled water will replace nearly all of the imported water used for injection into the DGSIB. **Table 3.3** presents average water quality data for the advanced treated recycled water produced by the TIWRP.

3.2.3 Quality of Stormwater

Stormwater infiltrates the subsurface to varying degrees throughout the WRD service area. It is also intentionally diverted from the major storm channels and used for groundwater recharge along with imported and recycled water at the Montebello Forebay Spreading Grounds. Routine stormwater quality analyses are performed by LACDPW and other entities. Average stormwater quality data provided by LACDPW for WY 2015-16 are presented on **Table 3.3**. The average TDS, manganese, chloride, nitrate, TCE, PCE, arsenic, and perchlorate concentrations in stormwater are relatively low. Iron exceeded drinking water standards, and was present in stormwater samples at much higher concentrations than in other sources.

3.3 MINERAL CHARACTERISTICS OF GROUNDWATER IN THE CBWCB

Major minerals data obtained from the WRD nested monitoring wells were used to characterize groundwater of discrete vertical zones (**Table 3.4**). Research by the USGS led to three distinct groupings of groundwater compositions. Group A groundwater is typically calcium bicarbonate or calcium bicarbonate/sulfate dominant. Group B groundwater has a typically calcium-sodium bicarbonate or sodium bicarbonate character. Group C has a sodium chloride character. A few of the WRD wells yield results that do not fall into one of the three major groups and are thus classified separately as Group D.

Groundwater from Group A likely represents recent recharge water containing a significant percentage of imported water. Group B represents older native groundwater replenished by natural local recharge. Group C represents groundwater impacted by seawater intrusion or connate saline brines. **Table 3.4** lists the groundwater group for each WRD nested monitoring well. Comparison of groundwater groups with well locations indicates that, in general, Group A groundwater is found at and immediately downgradient from the Montebello Forebay Spreading Grounds in all but the deepest zones. Group B groundwater is found farther down the flow path within the Central Basin and inland of the West Coast Basin Seawater Intrusion Barrier. Group C groundwater is generally found near the coastlines or in deeper zones. Several wells, grouped as “Other” on **Table 3.4**, exhibit a chemical character range different from Groups A, B, or C and indicate unique waters not characteristic of the dominant flow systems in the basins. The USGS is conducting ongoing research on trace element isotopes in water from these wells to identify their hydrogeologic source(s).

The major mineral compositions of water from the WRD nested monitoring wells sampled this WY have not changed substantially from previous years. It is expected that continued analysis will show gradual changes in major mineral compositions over time, as older native water is extracted from the basins and replaced by younger naturally and artificially replenished water.

SECTION 4
SALT AND NUTRIENTS IN GROUNDWATER

In February 2009, the SWRCB adopted Resolution No. 2009-0011, which established a statewide Recycled Water Policy (Policy). This Policy encourages increased use of recycled water and local stormwater for groundwater recharge across the State. It also requires local entities to develop a Salt and Nutrient Management Plan (SNMP) for each groundwater basin in California to monitor groundwater quality and any impact due to increased recycled water and stormwater recharge.

A SNMP Workplan was jointly prepared by the CBWCB stakeholders and approved by the Los Angeles Regional Water Quality Control Board (LARWQCB) in December 2011. The Final SNMP for the CBWCB was finalized February 12, 2015 and adopted in July 2015. The full text of the "2015 Salt Nutrient Management Plan – 2015" can be found at *http://www.wrd.org/content/other-reports*

The objective of the SNMP is to manage salts and nutrients from all sources "… on a basin-wide or watershed-wide basis in a manner that ensures attainment of water quality objectives and protection of beneficial uses." Future groundwater quality and assimilative capacity were calculated based on predicted salt and nutrient loading through 2025 in the CBWCB. Accordingly, current and proposed projects through 2025 were identified and used to develop strategies to manage salt and nutrient loading. The SNMP included the following:

- Stormwater and Recycled Water Use/Recharge Goals and Objectives,
- Characterization of the Hydrogeologic Conceptual Model/Water Quality,
- Estimation of Current and Future Salt and Nutrient Loading,
- A Basin-Wide Water Quality Monitoring Plan,
- Estimation of Salt and Nutrient Assimilative Capacity,
- An Anti-degradation Analysis,
- Implementation Measures to Manage Salt and Nutrient Loading, and
- California Environmental Quality Act (CEQA) analysis of the SNMP.

WRD's RGWMP was used to develop the SNMP monitoring program. The groundwater data evaluated in the annual RGWMRs provide an annual assessment of salt and nutrients in groundwater. In addition to the water quality maps generated and discussed in Section 3, historical trend graphs at key monitoring well locations, as described in the following sections, were used to assess salt and nutrient concentrations in groundwater.

4.1 SALT AND NUTRIENT MONITORING LOCATIONS

As discussed in the SNMP, TDS, chloride, and nitrate were identified as the most appropriate indicators of salt and nutrients in the CBWCB. These constituents, as well as other constituents of concern identified in the SNMP, are monitored in the WRD nested monitoring wells along with production wells located throughout the CBWCB.

As part of the SNMP monitoring program, 13 key monitoring well locations in the CBWCB were selected to evaluate past and current salt and nutrient concentrations in groundwater with respect to applicable water quality objectives (WQOs). As established in the Basin Plan, the WQO for TDS in the Central Basin and West Coast Basin is 700 mg/L and 800 mg/L, respectively; the WQO for chloride in the Central Basin and West Coast Basin is 150 mg/L and 250 mg/L, respectively; and the MCL/WQO in both basins for nitrate is 10 mg/L.

In accordance with the Recycled Water Policy, the 13 selected nested well locations are in the most critical areas of the basins, particularly their proximity to water supply wells and groundwater recharge projects that utilize recycled water, including the seawater intrusion barriers (Alamitos Gap Barrier, Dominguez Gap Barrier, and West Coast Basin Barrier) and the Montebello Forebay Spreading Grounds. There are three nested well locations in the Montebello Forebay, one in the Los Angeles Forebay, four in the Central Basin Pressure Area, one in the Whittier Area, and four in the West Coast Basin. Monitoring locations in the Montebello Forebay and Los Angeles Forebay target groundwater where connectivity with adjacent surface waters is possible.

The 13 key nested well locations are shown as a different symbol set on **Figure 1.3**. These locations include 70 individual monitoring zones, screened in specific CBWCB aquifers.

The depths and aquifer designation for these key monitoring wells are provided in **Table 1.1**. WRD is the entity, designated by the SWRCB, responsible for collecting TDS, chloride, and nitrate samples (on a semi-annual basis) from these nested wells.

4.2 SALT AND NUTRIENT MONITORING RESULTS AND EVALUATION

Concentrations of salt and nutrients have been and continue to be closely monitored in all WRD nested monitoring wells and purveyors' production wells and results are discussed in **Section 3**. Concentrations of TDS, chloride, and nitrate for all WRD nested wells sampled during WY 2016-17 are shown on maps (**Figures 3.1, 3.7, and 3.9**, respectively) and summarized along with other monitored constituents identified in **Tables 3.1** and **3.2**. TDS, chloride, and nitrate concentrations in production wells, sampled during WYs 2014-2017 are presented on maps (**Figures 3.2, 3.8**, and **3.10** respectively). Trends for TDS and chloride concentrations at the 13 key well locations discussed above in Section 4.1 are plotted on graphs and compared to SMCLs and WQOs (**Figures 4.1** through **4.13**). Nitrate generally has not been detected in the monitoring wells, or it has been detected only at concentrations significantly below the MCLs and WQOs, and thus, trend graphs for nitrate have not been prepared. However, nitrate will continue to be monitored as part of the RGWMP and will be reported in **Section 3** of the annual RGWMRs.

In the Montebello Forebay, TDS and chloride concentration trends for the key well locations Rio Hondo #1, Pico #2, and Norwalk #2 are presented on **Figures 4.1** through **4.3**, respectively. TDS and chloride concentrations have historically been and remain below the SMCLs and WQOs at all three well locations. Several middle zones at Rio Hondo #1 and Pico #2 show slight increasing trends for TDS and chloride, while concentrations in the shallow zones fluctuate more. Otherwise, trends do not indicate significant increasing salt concentrations in the Montebello Forebay.

In the Los Angeles Forebay, the key well is Huntington Park #1 (4 zones). TDS and chloride concentration trend graphs are shown on **Figure 4.4**. The deeper two zones of this well show stable trends for TDS and chloride at concentrations below the SMCLs and

WQOs. The upper two zones may indicate slight increases in TDS and chloride concentrations over the past four or five years, but these concentrations are still below the SMCLs. In the upper two zones chloride concentrations are below the WQO, but TDS concentrations are above the WQO of 700 mg/L.

In the Central Basin Pressure Area, key wells include South Gate #1 (5 zones), Willowbrook #1 (4 zones), Long Beach #6 (6 zones), and Seal Beach #1 (7 zones). TDS and chloride trends are shown on **Figures 4.5** through **4.8,** respectively. At South Gate #1, the four deeper zones show TDS and chloride concentrations at relatively consistent values below the SMCLs and WQOs. TDS and chloride concentrations in South Gate #1 Zone 5 have increased somewhat since initial sampling but are relatively stable over the past 9 years and are generally below both the WQOs and SMCLs. At all 4 zones of Willowbrook #1 and the upper four zones at Long Beach #6, TDS and chloride concentrations are quite stable and are below both the SMCLs and WQOs. In the two deepest zones of Long Beach #6, TDS is typically detected very close to the WQO of 700 mg/L, while chloride concentrations remain stable and are significantly below the SMCL and WQO. At Seal Beach #1, the deeper six zones contain TDS and chloride at concentrations below the WQOs and SMCLs. Zone 7, the shallowest zone, contains TDS and chloride concentrations that have been generally increasing and are well above the WQOs and SMCLs, likely due to seawater intrusion.

For the Whittier Area, represented by key well Whittier #1 (5 zones), TDS and chloride trends are shown on **Figure 4.9**. TDS in zones 4 and 5 has been stable over the past 15 years, is below the MCL, and meets the WQO. TDS in zones 1, 2, and 3 has historically exceeded the MCL and WQO, and generally shows a stable to slightly increasing trend. Chloride in zones 4 and 5 has been historically below the MCL and meets the WQO. Chloride in zones 1, 2, and 3 has historically exceeded the WQO, but has been historically below the SMCL, and generally shows a stable trend.

In the West Coast Basin, key wells include PM-4 Mariner (4 zones), Carson #1 (4 zones), Manhattan Beach #1 (7 zones), and Wilmington #2 (5 zones). TDS and chloride trends are presented on **Figures 4.10** through **4.13**, respectively. At PM-4 Mariner,

Zones 1, 3, and 4 show TDS and chloride at relatively consistent concentrations below the SMCLs and WQOs. However at PM-4 Mariner Zone 2, TDS and chloride concentrations are well above the SMCLs and WQOs and have increased since monitoring began around 1997. This is attributed to historical seawater intrusion prior to the construction of the West Coast Basin Seawater Barrier. At Carson #1, all four zones contain TDS and chloride concentrations below both the SMCLs and WQOs; here the three deeper zones show relatively stable TDS and chloride concentrations, while concentrations of these constituents in the shallow Zone 4 have decreased since initial sampling in 1998. At Manhattan Beach #1, groundwater in this coastal area indicates impacts from seawater intrusion. While this well was constructed in 2011 and thus only sampled eight times over the past six years, TDS concentrations in 5 of the 7 zones exceed the WQO and SMCL and in four zones the WQO and SMCL for chloride are exceeded. Additional sampling at Manhattan Beach #1 should allow concentration trends to be more clearly identified. At Wilmington #2, TDS in Zones 1 and 3 has historically been below the WQO and SMCL, while Zone 2 has been consistently above the WQO and SMCL. TDS and chloride in Zone 4 were initially above the WQOs and SMCLs, but have steadily decreased since and are now below the WQOs and SMCLs, due to the implementation measures discussed in Section 4.3 below. TDS and chloride in Zone 5 are much higher than the WQOs and SMCLs; however, they have steadily decreased and are currently at concentrations far below those observed during the first years of sampling.

4.3 IMPLEMENTATION MEASURES TO MANAGE SALT AND NUTRIENT LOADING

As summarized in the previous section, overall TDS and chloride concentrations are generally stable at most of the 13 key nested monitoring locations in the CBWCB. While a few individual zones show increasing trends, a comparable number show decreasing trends. Notably, TDS and chloride concentrations in the two shallowest zones at nested well location Rio Hondo #1 and the three shallowest zones at Pico #2, each of which is beneath and adjacent to the Montebello Forebay recharge basins, generally fluctuate within the same concentration range since 1998. At the key well location in the Los Angeles

Forebay, the shallow zones have variable TDS concentrations at and above the WQO, but deeper zones do not show increasing TDS levels. In the Central Basin Pressure Area, TDS concentrations in the shallowest zone at key well location South Gate #1 fluctuate slightly but remain relatively stable, and chloride concentrations have steadily decreased over the past five years. TDS and chloride concentrations in the four lower zones are stable. Key nested monitoring well locations near the coast, including PM-4 Mariner, Manhattan Beach #1, and Seal Beach #1, have zones that show increasing TDS and chloride concentration trends that can be attributed to historical seawater intrusion. In the relatively isolated Whittier Area, historically high TDS and chloride concentrations in the middle depth zones are stable and are not expected to fluctuate in response to anticipated management practices.

As discussed in the SNMP, TDS and chloride concentrations in the Central Basin are not expected to exceed WQOs in the future, and current and proposed projects in the basin are not expected to increase salt and nutrient concentrations above the available assimilative capacity. Two notable projects in the Central Basin include the increased use of advanced treated recycled water for injection at the Alamitos Gap Seawater Intrusion Barrier and the increased use of recycled water at the Montebello Forebay Spreading Grounds through the implementation of ARC (formerly known as GRIP) which includes tertiary treated and advanced treated recycled waters.

In the West Coast Basin, average TDS and chloride concentrations can exceed WQOs due to historical seawater intrusion. However, these concentrations are decreasing and are anticipated to achieve WQOs in the future due to implementation measures such as the increased use of advanced treated recycled water for injection at the West Coast Basin and DGSIB and the continued operation of the desalter wells located in Torrance.

Nitrate concentrations in the CBWCB remain low and are not expected to increase above the MCL or WQO in the future. Overall, the data show that salt and nutrient concentrations in groundwater are stable as a result of past and current groundwater management practices. Based on the existing water quality of the CBWCB and the future groundwater

quality as estimated from the SNMP analysis, existing and planned implementation measures appear adequate to manage salt and nutrient loading on a sustainable basis.

SECTION 5
SUMMARY OF FINDINGS

This Regional Groundwater Monitoring Report was prepared by WRD to provide a comprehensive review of groundwater conditions in the WRD service area during WY 2016-17. A summary of findings is presented below.

- Artificial replenishment activities combined with natural replenishment and controlled pumping have ensured a sustainable, reliable supply of groundwater in the WRD service area. Artificial replenishment water sources used by WRD include imported water supplied by the MWD, tertiary-treated recycled water produced by the CSDLAC, and advanced treated recycled water produced by WBMWD, the City of Los Angeles, and WRD.
- Groundwater levels are monitored continuously in the WRD service area throughout the year. The WRD nested monitoring wells show clear, significant differences in groundwater elevations between the various aquifers. The water level differences in these nested wells reflect both hydrogeologic and pumping conditions in the WRD service area. Vertical head differences between 1 and 90 feet occur between zones above and within the producing aquifers. The greatest head differences between aquifers tend to occur in the southern area (Long Beach) of the Central Basin and the inland, eastern areas (Gardena and Carson) of the West Coast Basin, while the smallest differences occur in the recharge area of the Montebello Forebay, and the southern area (Torrance) of the West Coast Basin which has merged aquifers.
- Hydrographs and groundwater elevations measured in basinwide nested monitoring wells and key production wells indicate increases and decreases across the Central and West Coast Basins during WY 2016-17. The increase in water levels can be partly attributed to above average precipitation over the WRD service area in WY 2016-17. In the unconfined Montebello Forebay water levels have increased; in the vicinity of the spreading grounds they have increased by as much as 29 feet, along

the western and southern reaches of the Forebay they have increased as much as 12 feet, and to the east they have increased by 20 feet. Across much of the unconfined Los Angeles Forebay water levels have increased in WY 2016-17 by about 3 feet; however, in the central portion of the Forebay water levels decrease as much as 3 feet and appear to be influenced by a localized area of groundwater depression. Whittier Area water levels have also increased in WY 2016-17; in the west they have increased by as much as 20 feet, in the east they are essentially unchanged from WY 2015-16.

- Water levels have generally increased across the rest of the Central Basin in WY 2016-17. In the north portion of the CBPA water levels have increased this year by as much as 10 feet; along the eastern edge of the CBPA water levels are as much as 27 feet higher than they were last year. Across most of the rest of the CBPA water levels are about 1 to 3 feet higher than they were last year. In the southern portion of the CBPA, along the Northeast Uplift, water levels are relatively unchanged from WY 2015-16. In the West Coast Basin, changes in water levels are variable. Water levels increased by as much as 5 feet across most of the coastal area and within much of the Long Beach Plain during WY 2016-17. Water levels did not change significantly over portions of the Carson/Torrance area and north into Lawndale and southwest Los Angeles. However, water levels increased by as much as 5 feet in Lomita and the western portions of Torrance. In the Gardena area a localized pumping hole shows water level decreases of as much as 11 feet; water level decreases of between 1 and 5 feet in the Hawthorne and northern Carson areas appear to be associated with that pumping hole.
- District wide, groundwater levels rose more than 7.0 feet, although across the Montebello Forebay region water levels rose an average of nearly 17 feet. Overall groundwater storage gain across the District was 84,400 AF; 77,400 AF of that was gained in the Montebello Forebay. Groundwater storage gain in the Los Angeles Forebay was 2,700 AF, 1,200 AF of storage was gained in the Central Basin Pressure Area, and the Whittier Area saw in increase of 3,100 AF. In the West Coast Basin, there was no appreciable change in storage during WY 2016 – 17.
- Based on data obtained from WRD nested monitoring wells during WY 2016-

17, the water quality of key constituents in groundwater varies significantly across the WRD service area.

- TDS concentrations in WRD nested monitoring wells and purveyor production wells located in the Central Basin are relatively low, while those in the West Coast Basin are elevated in certain portions, primarily the coastal areas from Redondo Beach to LAX and the Inglewood and Dominguez Gap areas. The elevated TDS concentrations may be caused by seawater intrusion, connate brines, or possibly oil field brines.
- Iron generally is present at low levels in most WRD nested monitoring wells. In the Central Basin, concentrations were below the SMCL in the Silverado Aquifer at 30 of 33 nested well locations. In the West Coast Basin, iron concentrations were below the SMCL in the Silverado Aquifer at 18 of 22 nested well locations. Iron was detected below the SMCL in 164 of 224 production wells in the Central Basin and 11 out of 28 production wells in the West Coast Basin.
- Manganese is a naturally-occurring groundwater contaminant and negatively impacts a number of wells in the CBWCB. Manganese concentrations exceed the SMCL in the Silverado Aquifer at 9 out of 33 nested monitoring well locations in the Central Basin and at 13 out of 22 nested well locations in the West Coast Basin. Manganese concentrations were below the SMCL in 190 out of 227 production wells in the Central Basin and 10 out of 28 production wells sampled in the West Coast Basin.
- Chloride concentrations are reasonably low in Central Basin monitoring wells and production wells, and in wells within the inland areas of the West Coast Basin. Some coastal areas of the West Coast Basin are impacted by seawater intrusion and thus, have high chloride levels in groundwater.
- Nitrate (measured as nitrate) has an MCL of 45 mg/L, which corresponds to 10 mg/L nitrate as nitrogen. Nitrate concentrations in WRD nested monitoring wells in the CBWCB are generally below the MCL. The few nested wells that have nitrate concentrations approaching or exceeding the MCL tend to be limited to the uppermost zone at a given location and are likely due either to localized surface recharge, or isolated areas of shallow impacts from industrial operations. In the

Central Basin nitrate concentrations above the MCL were not observed in the Silverado Aquifer in any nested monitoring well; in the West Coast Basin, nitrate above the MCL in the Silverado Aquifer was only observed in two nested wells. DDW data indicates that one Central Basin production well had nitrate levels over the MCL. No West Coast Basin production wells contained nitrate at concentrations greater than the MCL.

- The MCL for TCE in drinking water is 5 µg/L. TCE was below the MCL in 30 out of 33 nested monitoring well locations in the Central Basin and 20 out of 22 nested well locations in the West Coast Basin. DDW data indicate that TCE was detected in 55 production wells in the Central Basin during the period spanning WYs 2014-17, and 20 of the 55 detections exceed the MCL. In the West Coast Basin, TCE was not detected above the MCL in any of the production wells tested.
- The MCL for PCE in drinking water is 5 µg/L. PCE was detected above the MCL at 2 nested monitoring well locations in the Central Basin. PCE was not detected above the MCL in any nested monitoring well locations in the West Coast Basin. DDW data indicate that PCE was detected in 53 production wells in the Central Basin during the period spanning WYs 2014-17; 14 of the 53 detections exceed the MCL. PCE was not detected in any of the West Coast Basin production wells.
- The MCL for arsenic is 10 µg/L. Arsenic concentrations greater than the MCL were found at 8 out of 33 nested monitoring well locations in the Central Basin and at 4 out of 22 nested well locations in the West Coast Basin. During the three year 2014-17 period, 8 out of 223 production wells tested in the Central Basin had arsenic concentrations above the MCL. Arsenic was not detected above the MCL in any West Coast Basin production wells.
- The MCL for perchlorate in drinking water is 6 µg/L. In the Central Basin, perchlorate was detected at 17 out of 33 nested monitoring well locations at concentrations below the MCL; eight of the detections were in the Silverado zone. In the West Coast Basin, perchlorate was detected at 6 out of 22 nested monitoring well locations, with perchlorate in one nested well above the MCL. Perchlorate was detected below the MCL in the Silverado zone at one nested monitoring well location in the West Coast Basin. In Central Basin production wells, 6 out

of 226 wells tested had detectable perchlorate; two of these wells had perchlorate concentrations above the MCL. Perchlorate was not detected in any of the West Coast Basin production wells.

- The historic MCL for hexavalent chromium of 10 µg/L was invalidated by the Superior Court of California in May 2017. WRD will continue to discuss hexavalent chromium results with reference to the concentration of 10 µg/L until a new MCL is established by the SWRCB. Hexavalent chromium can occur naturally in groundwater and/or be introduced through industrial and commercial activities. Hexavalent chromium was detected above the MCL in 2 out of 33 nested wells in the Central Basin. Hexavalent chromium was not detected above the MCL at any nested well in the West Coast Basin. Hexavalent chromium was not detected above the MCL in any Central Basin or West Coast Basin production well.
- 1,4-Dioxane is a synthetic organic compound. It is used as a stabilizer for solvents (in particular 1,1,1-trichloroethane) and as a solvent itself in a number of industrial and commercial applications. 1,4-Dioxane is also found in trace amounts in some cosmetic and personal care products such as detergents and shampoos. 1,4-Dioxane is highly soluble in water, does not readily bind to soils, readily leaches to groundwater, and is resistant to naturally occurring biodegradation processes. In the Central Basin, 1,4-Dioxane was detected in 14 of 32 nested wells, seven of those detections were in Silverado zones, and all detections were at concentrations above the NL. In the West Coast Basin, 1-4 Dioxane was detected at 1 of 18 nested well locations in a non-Silverado Aquifer zone. In the Central Basin, 1,4-Dioxane was detected in 79 of the 107 production wells that were tested. In the West Coast Basin, testing for 1,4-Dioxane was only conducted on 4 production wells. 1,4-Dioxane was not detected in any of those production wells.
- The NL for TBA is 12 µg/L. TBA is a fuel oxygenate and breakdown by-product of methyl tert-butyl ether (MTBE). TBA was detected above the NL at one nested monitoring well in the Central Basin. In the West Coast Basin, TBA was detected above the NL at two nested well locations. In the Central Basin, only 3 production wells were tested for TBA; it was not detected in any of those wells. In the West Coast Basin, testing for TBA was conducted on 6 production wells. TBA was not

detected above the NL in any of the West Coast Basin production wells.

- The water quality of key constituents in untreated imported water recharged at the Montebello Forebay Spreading Grounds and treated imported water injected at the seawater barriers remains in compliance with regulatory limits. Average TDS, iron, manganese, chloride, nitrate, arsenic, and hexavalent chromium concentrations in imported water used for recharge do not exceed their respective MCLs. Meanwhile, TCE, PCE, and perchlorate were not detected in the untreated imported water.
- The water quality of key constituents in recycled water used for recharge at the Montebello Forebay Spreading Grounds and injection at the seawater intrusion barriers complies with regulatory limits and is monitored regularly to ensure its safe use.
- Stormwater samples are collected and analyzed for various water quality parameters by the LACDPW and other entities in the CBWCB. Available data from LACDPW for WY 2015-16 show that average TDS and other constituent concentrations in stormwater are lower than most other sources of replenishment water and other constituent concentrations confirm that stormwater is a good replenishment source.
- A total of 13 WRD nested groundwater monitoring wells across the CBWCB were designated for salt and nutrient (specifically, TDS, chloride, and nitrate) sampling and reporting as part of the SNMP monitoring program. Based on water quality maps and trend graphs that were evaluated in this report, overall TDS and chloride concentrations are generally stable at most of the 13 key nested monitoring locations in the CBWCB. While a few individual zones show increasing trends, a comparable number show decreasing trends. Nitrate concentrations remain below the MCL at all 13 monitoring locations. In the Central Basin, average TDS and chloride concentrations do not currently exceed WQOs and are not expected to do so in the future. In the West Coast Basin, average TDS and chloride concentrations exceed WQOs locally due to historical seawater intrusion. However, these concentrations are decreasing and are anticipated to achieve WQOs in the future as a result of current groundwater management practices.
- As shown by the data presented herein, groundwater in the WRD service area is of

generally good quality and is suitable for use by the pumpers in the District, the stakeholders, and the public. Groundwater from localized areas with marginal to poor water quality can still be utilized but may require treatment prior to being used as a potable source.

SECTION 6
FUTURE ACTIVITIES

WRD will continue to update and augment its RGWMP to best serve the needs of the District, the pumpers, and the public. Some of the activities planned or which utilize data generated from this program for the current WY 2017-18 are listed below.

- WRD will continue to maximize recycled water use at the Montebello Forebay Spreading Grounds without exceeding regulatory limits; recycled water is a high quality, reliable, and relatively low-cost replenishment water source. Due to the scarcity of imported replenishment water deliveries from MWD, WRD developed the Water Independence Now (WIN) initiative, which includes increasing the safe use of recycled water for groundwater recharge and reducing reliance on imported water supplies. A key component of the WIN program is ARC (formerly known as GRIP), which is designed to ensure reliable sources of high quality replenishment water for groundwater users in the WRD service area. ARC is expected to begin operations in late 2018.
- WRD will continue to maximize recycled water use at the West Coast Basin Seawater Intrusion Barrier and will promote maximum permitted recycled water injection at the Dominguez Gap and Alamitos Gap Seawater Intrusion Barriers. All three of these Barriers are now permitted for 100% recycled water injection. Extensive groundwater monitoring of these major recycled water projects will continue to be performed by WRD to comply with permit conditions and applicable regulatory requirements and to track subsurface movement of the recycled water.
- WRD will continue to monitor the quality of replenishment water sources to ensure the CBWCB are being recharged with high-quality water.
- WRD continues refining the regional understanding of groundwater occurrence, movement, and quality. Water levels will continue to be recorded using automatic dataloggers to monitor groundwater elevation differences throughout the year. Conductivity sensors are being utilized at selected nested monitoring wells to track

water quality changes and supplement the automated water level data. Telemetry technology is being implemented to send real-time water level data to WRD from several locations with a goal of real-time display of water levels on the WRD website. A Supervisory Control and Data Acquisition (SCADA) system is being developed which will allow electronic transfer of water level data from the source of measurement to a centralized location which can be accessed remotely for real-time data observation and analysis.

- WRD continually evaluates the need to fill data gaps in water level data, water quality data, and the hydrogeologic conceptual model with additional geologic data provided from drilling, construction, and monitoring of nested wells. Two such wells are planned for installation in the North Central Basin to expand WRD's monitoring network into that area as part of CASGEM and SGMA compliance, in addition to providing data needs for groundwater flowing into WRD's service area.
- WRD will continue to sample groundwater from nested monitoring wells, and analyze the samples for general water quality constituents. In addition, the focus will continue on constituents of interest to WRD, the pumpers, and other stakeholders, such as TCE, PCE, manganese, arsenic, perchlorate, and hexavalent chromium. As regulators consider new water quality standards for CECs which have not been comprehensively monitored in the past, WRDs nested monitoring well network is well positioned to screen for emerging CECs in groundwater which may include, pesticides, NDMA, 1,4-dioxane, pharmaceuticals and personal care products, oil and gas field indicators, and other CECs. This year WRD anticipates filling database gaps by analyzing groundwater samples for constituents such as 1,2,3-Trichloropropane (1,2,3-TCP), and NDMA in wells where such data has not been previously collected. WRD will be working on refining the hydrogeologic conceptual model of the CBWCB using data from the RGWMP along with an update to the groundwater model, expected to be finalized in 2018, that has been developed by the USGS to improve the framework for understanding the groundwater system and for use as a planning tool.
- WRD will continue efforts under its Groundwater Contamination Prevention Program in order to minimize or eliminate threats to groundwater supplies. The Groundwater Contamination Prevention Program includes several ongoing efforts, including the

CBWCB Groundwater Contamination Forum with key stakeholders that include the USEPA, California Department of Toxic Substances Control, LARWQCB, DDW, USGS, and various cities and other water purveyors. Stakeholders meet regularly and share data on contaminated groundwater sites within the District. WRD acts as the meeting coordinator and data repository/distributor, helping stakeholders to characterize the extent of contamination to identify pathways for contaminants in shallow aquifers to reach deeper drinking water aquifers and develop optimal methods for remediating contaminated groundwater. With input from the Forum members, WRD has developed a list of high-priority contaminated groundwater sites within the District. The list currently includes 49 sites located throughout the CBWCB.

- WRD will continue to be proactively involved in the oversight of the most significant contaminated sites that threaten groundwater resources within its service area including the ongoing regional perchlorate investigation in the Los Angeles Forebay, the Omega Chemical Superfund Site in the eastern portion of the Central Basin, the Montrose/Del Amo site in the eastern West Coast Basin, the Whittier Narrows Operable Unit north of the Montebello Forebay area and others.
- WRD will continue to fund the Safe Drinking Water Program to address impacted groundwater (both naturally occurring and anthropogenic), especially by PCE and TCE in the WRD service area. The WRD Safe Drinking Program now includes special assistance for water systems located in disadvantaged communities within the District's service area. This new extension is the Safe Drinking Water Disadvantaged Communities (DAC) outreach program.
- Consistent with WRD's mission to provide, protect, and preserve high quality groundwater and as required by the State's Recycled Water Policy, a SNMP is now in place and being implemented. Based on the existing water quality of the CBWCB and results from the SNMP analysis, it has been shown that salt and nutrient loading to groundwater is not a concern and that salt and nutrient concentrations overall in groundwater are either stable or improving due to past and current groundwater management practices. Existing and planned implementation measures are protective of groundwater quality and its beneficial uses and the increased use of recycled water in the WRD service area is consistent with the goals of the Recycled Water Policy and

necessary to ensure a sustainable water supply.

- On November 4, 2009 the State Legislature amended the Water Code with SBx7-6, mandating a statewide groundwater elevation monitoring program to track seasonal and long-term trends in California's groundwater basins. In accordance with this amendment DWR developed the CASGEM program. In October 2011, WRD was assigned as the Designated Monitoring Entity responsible for collecting and reporting CBWCB groundwater level data to CASGEM. Through the RGWMP, WRD will continue to collect CBWCB groundwater level data, track seasonal and long-term trends and provide the data to the CASGEM program.
- WRD has worked closely with various stakeholders to comply with the Sustainable Groundwater Management Act (SGMA). SGMA recognizes groundwater as an integral part of the state's water supply and provides a framework for managing groundwater in a sustainable way throughout California. SGMA applies to two areas located within the geologic boundaries of the Central Basin but outside of its adjudicated boundaries. To comply, a working group was formed to conduct a groundwater sustainability analysis with various interested stakeholders including the City of Beverly Hills, City of Culver City, LACDPW, LADWP, Golden State Water Company (GSWC), and WRD. On behalf of the stakeholder group WRD submitted the required analysis to the DWR in the document, "Alternative Analysis for the Central Basin – Los Angeles County, California", dated December 16, 2016 (WRD, 2016). WRD expects to receive an evaluation update from the DWR in 2018.
- WRD will continue to use the data generated by the RGWMP along with WRD's GIS capabilities to address current and potential water quality issues and groundwater replenishment in its service area.

TABLE 3.3
QUALITY OF REPLENISHMENT WATER

Notes:

A = Used at the seawater intrusion barriers: generally, Diemer Plant effluent / Jensen Plant effluent (Data Source #1).

B = Used at the Montebello Forebay spreading grounds (Lake Mathews) (Data Source #1).

C = Used at the Montebello Forebay spreading grounds (Silverwood Lake) (Data Source #1).

D = Effluent of Edward C. Little Water Recycling Facility (ELWRF) before blending with treated water from Colorado River/State Water Project; used at the West Coast Basin Seawater Intrusion Barrier (Data Source #4).

E = Effluent of Terminal Island Water Reclamation Plant/Advanced Water Treatment Facilities (TIWRP) before blending with treated water from Colorado River/State Water Project; used at the Dominguez Gap Seawater Intrusion Barrier. Estimated values used where reported as "detected, but not quantified" [DNQ] (Data Source #6).

F = Effluent of Leo J. Vander Lans Advanced Water Treatment Facility (LVL AWTF) before blending with treated water from Colorado River/State Water Project; used at the Alamitos Gap Seawater Intrusion Barrier (Data Source #7).

G = Effluent of water reclamation plants (WRPs); used at the Montebello Forebay spreading grounds (Data Source #3).

H = Average concentration of water samples collected from LACDPW San Gabriel River Monitoring Station S14 from December 2016 through March 2017 (four storm events total) (Data Source #5).

I = Average concentration for Water Year October 2015 through September 2017 (Data Source #2).

J = Average concentration in blended water (treatment plant effluent & treated water from Colorado River/State Water Project), which is delivered to the West Coast Basin Seawater Intrusion Barrier (Data Source #4).

K = Average concentration in blended water (treatment plant effluent & treated water from Colorado River/State Water Project), which is delivered to the Dominguez Gap Seawater Intrusion Barrier (Data Source #6).

L = Average concentration in blended water (treatment plant effluent & treated water from Colorado River/State Water Project); directly used at the Alamitos Gap Seawater Intrusion Barrier (Data Source #7).

M = California's 2014 Groundwater Replenishment Using Recycled Water Regulations specify the following TOC limits for groundwater replenishment projects:

- For surface spreading (surface application), TOC limit = 0.5 mg/L divided by the 120-month running monthly average recycled water contribution (e.g., the TOC limit for a 100% recycled water project would be 0.5 mg/L.) For compliance determination, TOC may be monitored in one of the following: 1) undiluted recycled municipal wastewater prior to application or within the zone of percolation; 2) diluted percolated recycled municipal wastewater, with the value amended to negate the effect of the diluent water; or 3) undiluted recycled municipal wastewater prior to application, with the value amended using a soil-aquifer treatment factor approved by the Division of Drinking Water.
- For injection (subsurface application), TOC limit = 0.5 mg/L. For compliance determination, TOC is monitored in the applied recycled municipal wastewater.

NA = Not Available/Analyzed
ND = Not Detected
NS = Not sampled due to plant shutdown
mg/L = milligrams per liter
µg/L = micrograms per liter
µS/cm = microSiemen per centimeter

NTU = Nephelometric Turbidity Units
MCL = Maximum Contaminant Level
SMCL = Secondary Maximum Contaminant Level
AL = Action Level
NL = Notification Level
WRP = Water Reclamation Plant

LACDPW = Los Angeles County Department of Public Works
LADWP = Los Angeles Department of Water and Power
MWD = Metropolitan Water District of Southern California
SDLAC = County Sanitation Districts of Los Angeles County
WBMWD = West Basin Municipal Water District
WRD = Water Replenishment District of Southern California

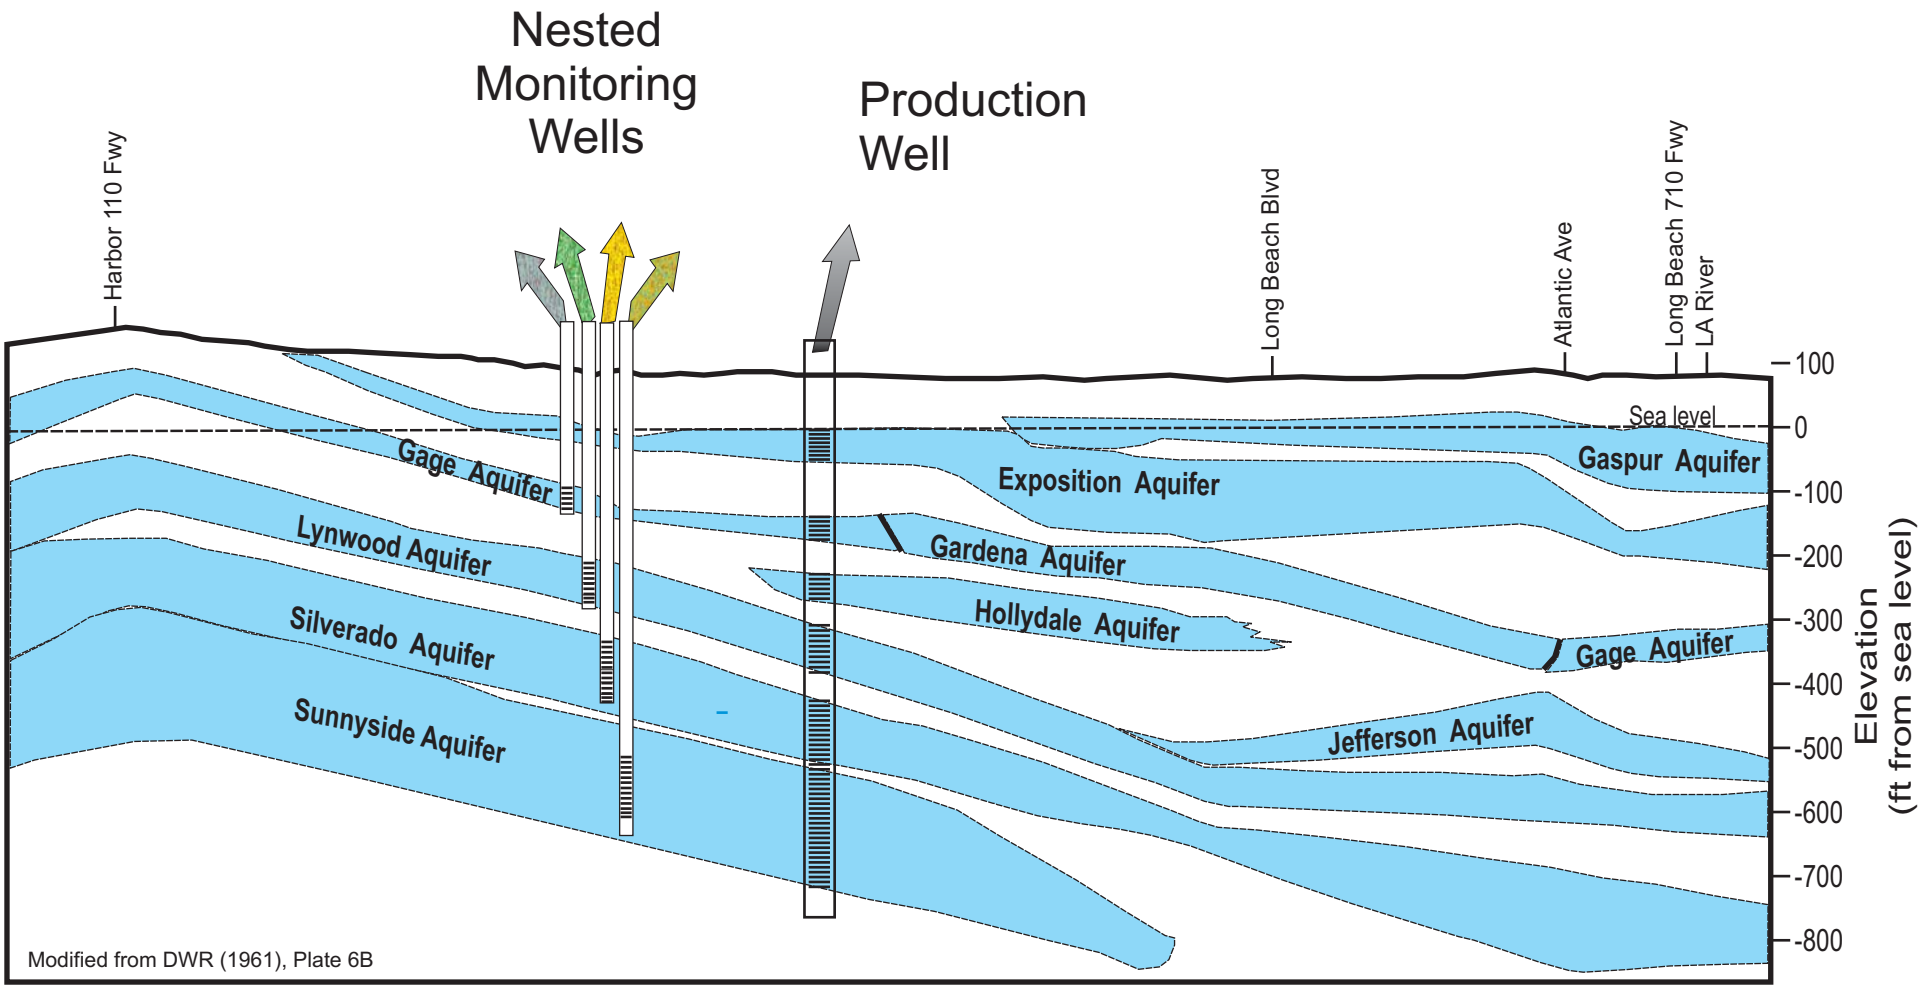
FIGURE 1.2
NESTED WELLS vs. PRODUCTION WELLS
FOR AQUIFER-SPECIFIC DATA



Production wells are typically perforated across multiple aquifers producing an average water quality. Nested monitoring wells are screened in a portion of a specific aquifer, providing water quality and water level information for the specific zone.
